> Abstracts

This report is an update and extension of the previously published reports on pollutant emissions from road transport in Switzerland. It now covers the period from 1990 to 2035 and presents detailed emission factors that have been obtained from internationally co-ordinated studies for all road vehicles and for various regulated and non-regulated air pollutants and greenhouse gases. Total emissions have been projected on the basis of traffic data recorded in Switzerland. Generally speaking, the findings confirm previous forecasts. New findings have been obtained, primarily relating to particle and nitrogen oxide emissions, as well as cold-start emissions, and these mainly result from new measurements carried out on older vehicles. Thanks to the inclusion of new exhaust regulations that have been introduced since the publication of the previous report (SAEFL Report 355 2004), the forecasts in this report now assume a more pronounced reduction of pollutant emissions than was previously anticipated. The significant differences between standard and real data are a problem that has yet to be resolved.

This report serves as a useful tool for all groups focusing on the development of air pollutant emissions from road transport, and the findings will flow into evaluations of future measures and projects, as well as into national and international statistics.

Der Bericht stellt eine Aktualisierung und Fortführung der bisher erschienenen Unterlagen zu den Luftschatstoffemissionen des Strassenverkehrs in der Schweiz dar. Er deckt neu den Zeithorizont von 1990 bis 2035 ab. Aus den international abgestimmten Emissionsuntersuchungen wurden detaillierte Emissionsfaktoren für alle Strassenfahrzeuge und für diverse reglementierte und nicht limitierte Luftschatstoffe und Klimagase ermittelt. Gestützt auf die in der Schweiz erhobenen Verkehrsdaten wurden die Gesamtemissionen berechnet. Die Ergebnisse bestätigen die bisherigen Prognosen mehrheitlich. Neue Erkenntnisse ergaben sich hauptsächlich bei den Partikel- und den Stickoxid-Emissionen sowie bei den Kaltstart-Emissionen. Diese Erkenntnisse sind vor allem neuen Messungen auch an älteren Fahrzeugen zu verdanken. Der Einbezug der seit der letzten Berichterstattung (Schriftenreihe Umwelt Nr. 355, BUWAL 2004) beschlossenen zukünftigen Abgasvorschriften trägt dazu bei, dass die neuen Prognosen von einer noch stärkeren Absenkung der Schadstoffemissionen ausgehen als bisher angenommen. Ein nach wie vor ungelöstes Problem stellen die grossen Abweichungen zwischen Standard- und Realdaten dar.

Der Bericht ist eine gute Grundlage für alle an der Entwicklung der Luftschatstoffemissionen interessierten Kreise. Die Resultate werden in die Beurteilung zukünftiger Massnahmen und Projekte sowie in nationale und internationale Statistiken einfließen.

Ce rapport actualise et développe les documents publiés à ce jour sur les émissions de polluants atmosphériques produites par le trafic routier en Suisse. Il couvre maintenant la période 1990 à 2035. S'appuyant sur des études d'émissions, coordonnées à l'échelon international, les auteurs ont élaboré des coefficients d'émission détaillés pour l'ensemble des véhicules routiers, de même que pour divers polluants atmosphériques et gaz à effet de serre réglementés ou non limités. Toutes les émissions ont été extrapolées sur la base des données des transports relevées en Suisse. Les résultats confirment largement les prévisions faites jusqu'à présent. On a cependant acquis de nouvelles connaissances, notamment en ce qui concerne les émissions de particules et d'oxydes d'azote, de même que les émissions à froid, grâce, surtout, aux nouvelles mesures également effectuées sur des véhicules anciens. Comme le présent rapport intègre les futures prescriptions sur les gaz d'échappement entérinées depuis le dernier rapport (Cahier de l'environnement n° 355, OFEFP 2004), les nouvelles prévisions qu'il contient tablent sur une baisse des émissions polluantes encore plus forte que supposée jusqu'ici. Les écarts importants entre données normalisées et données réelles restent toutefois un problème.

Le rapport est une bonne base pour tous les milieux intéressés par l'évolution des émissions de polluants atmosphériques. Ses résultats trouveront des applications dans l'évaluation de mesures et de projets futurs, ainsi que dans les statistiques nationales et internationales.

Il rapporto costituisce un aggiornamento e sviluppo delle pubblicazioni esistenti in materia di emissioni di inquinanti atmosferici provocate dal traffico stradale in Svizzera. Rispetto alle pubblicazioni precedenti copre un periodo compreso tra il 1990 e il 2035. A partire dagli studi sulle emissioni, coordinati a livello internazionale, sono stati rilevati fattori di emissione dettagliati per tutti i veicoli stradali e per diversi inquinanti atmosferici e gas serra, regolamentati e non. Sulla base dei dati sul traffico raccolti in Svizzera sono in seguito state estrapolate le emissioni totali. I risultati hanno per lo più confermato le previsioni, fornendo tuttavia anche elementi nuovi, soprattutto per quanto riguarda le emissioni di particolato e di ossidi d'azoto, così come per le emissioni dell'avviamento a freddo. Questo stato delle conoscenze è frutto in particolare delle nuove misurazioni effettuate anche su veicoli vecchi. L'integrazione delle future prescrizioni concernenti i gas di scarico, elaborate dopo la pubblicazione dell'ultimo rapporto (Scritti sull'ambiente n. 355, UFAFP 2004), consente alle nuove previsioni di considerare una riduzione delle emissioni di sostanze nocive ancora più importante di quanto previsto fino ad ora. La significativa differenza fra dati normativi e dati reali costituisce tuttora un problema irrisolto.

Il rapporto rappresenta un riferimento utile per tutti gli ambienti interessati all'andamento delle emissioni degli inquinanti atmosferici. I risultati confluiranno nella valutazione di provvedimenti e progetti futuri, così come nelle statistiche nazionali e internazionali.

> Foreword

Road transport is a major source of air pollution and a significant factor in climate change. In order to reduce traffic-related air pollutants and CO₂, we need to gain precise information about the emission behaviour of motor vehicles. To keep the findings up to date in an environment of constantly developing technologies and regulations, hundreds of vehicles were measured in the framework of internationally co-ordinated programmes. This made it possible to reliably calculate emission factors for air pollutants and CO₂, incorporate new vehicle technologies and exhaust emission levels into the calculations, and make projections and forecasts regarding air pollutant emissions from road transport. The resulting data are integrated into national and international inventories of pollutants and climate gases.

This study shows that the introduction of new exhaust regulations has resulted in a significant decrease in the emissions of CO, HC, NO_x and particles, and will continue to do so in the future. However, additional measures are still required in order to secure compliance with ambient limit values for human health and environmental quality, and with internationally defined critical pollution levels for sensitive ecological systems. Another problem that has to be overcome concerns the high level of CO₂ emissions, which are a significant factor in the process of climate change.

Most of the findings in this report confirm the figures in earlier studies for present-day emissions and predicted future reductions. However, discrepancies were identified, mainly for older vehicles, and in connection with hydrocarbons and nitrogen emissions from motorcycles and passenger cars. The predictions regarding traffic volumes have been somewhat adjusted compared to earlier forecasts.

This study was supported by the Federal Roads Office (FEDRO). Thanks to its comprehensive data on emissions from road transport, it will serve as an important tool for evaluating specific projects and assessing measures aimed at reducing emissions of air pollutants and greenhouse gases from motorised road traffic.

Gérard Poffet
Vice Director
Federal Office for the Environment (FOEN)

> Summary

Measuring pollutant emissions from road transport has a lengthy tradition in Switzerland. The first SAEFL report on this topic (no. 55) dates back to the mid-1980s, and this was followed up by comprehensive and internationally co-ordinated research activities that were concluded in 1995 with the publication of "Report 255" and version 1 of the emission factors handbook (HBEFA 1.1). A supplement was then published in 2000, and this was followed by "Report 355" in 2004. The present report is a further update of the emission forecasts. In parallel, the emission factors handbook has also been revised and updated, and is now available on the Internet as version 3.1. Here, various aspects have been standardised in line with the increasingly international focus, and a variety of criteria for the calculation of emission factors have been added. New emission measurements have been included, and the official new Euro categories of emission standards (Euro-5 and Euro-6 for light duty vehicles, and Euro-V and Euro-VI for heavy duty vehicles) have been taken into account.

The traffic composition data have also been updated. As before, traffic volume is expected to increase, though probably with growth rates slower than in the past. For both passenger cars and goods vehicles, the anticipated increase as of 2035 is estimated at around 20 per cent versus 2010. The estimated mileage figures for passenger cars are only slightly higher compared to Report 355. The figures for light duty vehicles were re-estimated – also retroactively – by the Federal Statistical Office (FSO) following the introduction of the heavy goods vehicle fee, and have been significantly adjusted downwards. By contrast, the data relating to heavy duty vehicles are practically unchanged compared with the previous report. Viewed in absolute terms, the mileage of buses is comparatively low. According to the FSO, the mileage figures for coaches have increased, and higher growth is assumed for buses than was predicted by the previous study (plus 27 per cent in 2035 versus 2010). As far as motorcycles are concerned, mileage figures have increased at a slightly slower pace than was previously anticipated. In view of this, the growth rate in this category has been correspondingly reduced, but at 25 per cent it is slightly higher than those for passenger cars and heavy duty vehicles.

Figure A shows the pollutant emissions by vehicle category over a time series ranging from 1990 to 2035. As we can see, the pollutant emissions fall continuously and sharply thanks to the introduction of a succession of more stringent limit values. However, there are differences in the extent and pattern of the decrease, depending on the pollutant: the reductions of carbon monoxide (CO) and hydrocarbons (HC) have been pronounced up till now. These emissions primarily result from passenger cars: they are largely attributable to cold-starts, and will be even more so in the future. Furthermore, the proportions of CO and HC emissions from motorcycles are high compared with the mileage figures. Over the long term, CO and HC emissions can be expected to fall again by around 50 per cent with respect to the present-day levels, despite a higher traffic volume.

In the case of nitrogen oxide (NO_x) and particle emissions, the previous reduction rate has slowed down. This is due on the one hand to lower specific reductions for passenger cars (in grams per kilometre), and on the other hand to the contribution of heavy duty vehicles which are also relevant sources of NO_x and PM emissions. Furthermore, the limits values were introduced in the legislation later for this group than for light duty vehicles. However, further significant reductions are to be expected thanks to the introduction of more stringent limit values (Euro-VI). The trend in particle emissions is worthy of note: it has been influenced by the increasing proportion of diesel passenger cars over the past ten years (currently amounting to about 30 per cent in the new cars segment). However, the progressive spread of diesel particle filters should result in a sharp reduction in PM exhaust emissions.

The trend of CO_2 emissions differs greatly from that of NO_x and PM exhaust emissions: in the road transport sector, CO_2 emissions reached their peak between 2000 and 2010. The trend depicted represents a “business as usual” scenario, which assumes that, in the passenger cars segment, the previously determined reduction in fuel consumption by new vehicles (approximately minus 1.5 per cent annually on average between 2000 and 2008) remains constant all the way up to 2035. No significant specific reductions are assumed for the other vehicle categories. Based on these assumptions, after reaching a peak of 14.4 million tonnes in 2010, the level of CO_2 emissions from road transport will fall to around 12.8 million tonnes in 2030, which more or less corresponds to the level recorded in 1990. This means that a downward trend is also assumed for CO_2 emissions, but to a lower extent than that for NO_x and PM emissions.

Figure B shows the updated emission trends compared with the 2004 Report 355. Generally speaking, these do not differ greatly from the previous calculations. The most notable change concerns particle emissions, and this is attributable to the use of different methods to determine emission factors (in Report 355, the estimates of particulate matter emissions of older and not yet regulated heavy duty vehicles were higher). Furthermore, there is now a sharper decline after 2020 than was anticipated in 2004 by Report 355. This is attributable to the inclusion of the new emission standard categories (Euro-5/V and Euro-6/VI). Another notable trend is that the actual reductions have occurred more slowly than was anticipated a few years ago. This applies especially to NO_x emissions, which have now been raised by approximately 20 per cent for 2010, primarily due to an upward adjustment of the emission factors for passenger cars (diesel Euro-3 and Euro-4). Up to 2020, CO_2 emissions are forecast as more or less constant. The difference from 2020 onwards, despite assuming the same reduction rate, is due to a stabilisation having been anticipated after 2020 in Report 355. The updated prognosis results from new technologies and recently adopted measures to reduce CO_2 emissions due to traffic.

Finally, the trend of air pollutant emissions from road transport correlates well with that of ambient loads from all sources, as exemplified by the data for nitrogen oxides from 1991 onwards: for the period up to 2009, both the modelled emissions from road transport and the ambient levels have gone down by almost 50 per cent. Nonetheless, additional measures are still required in order to meet the ambient limit values for human health and environmental quality.

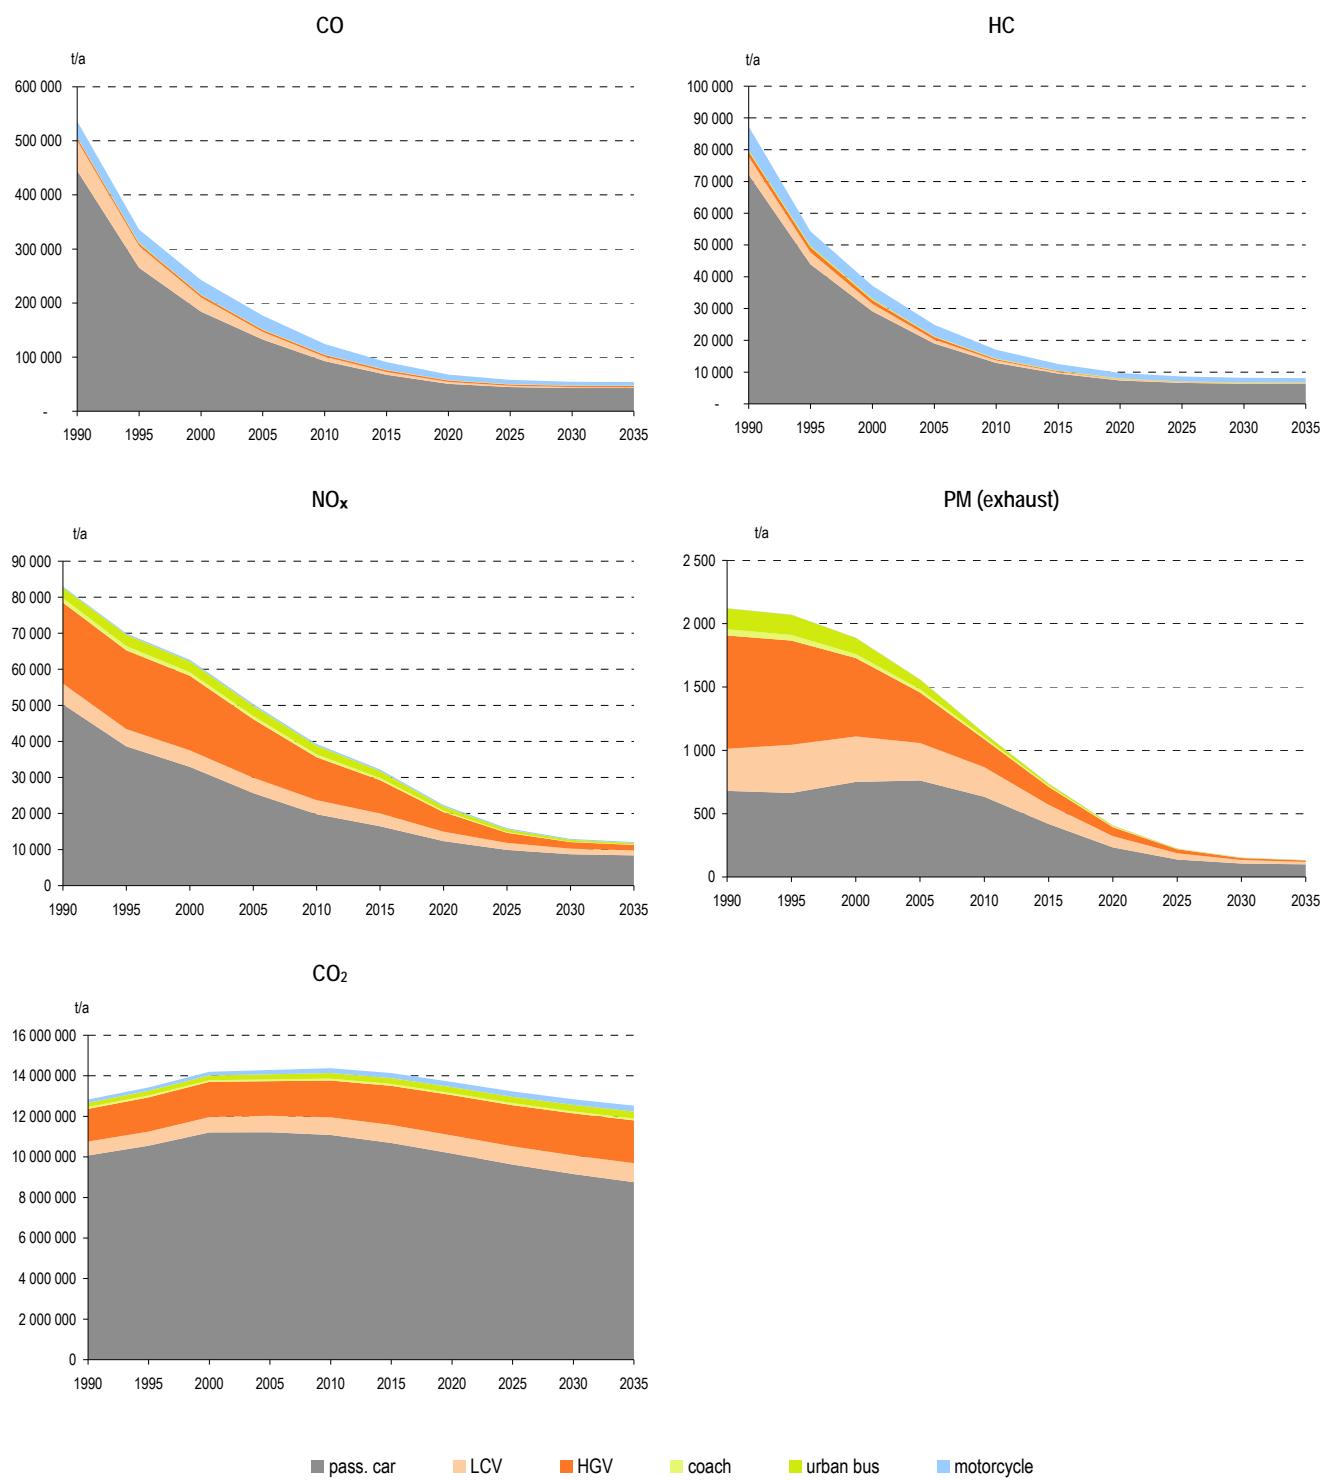

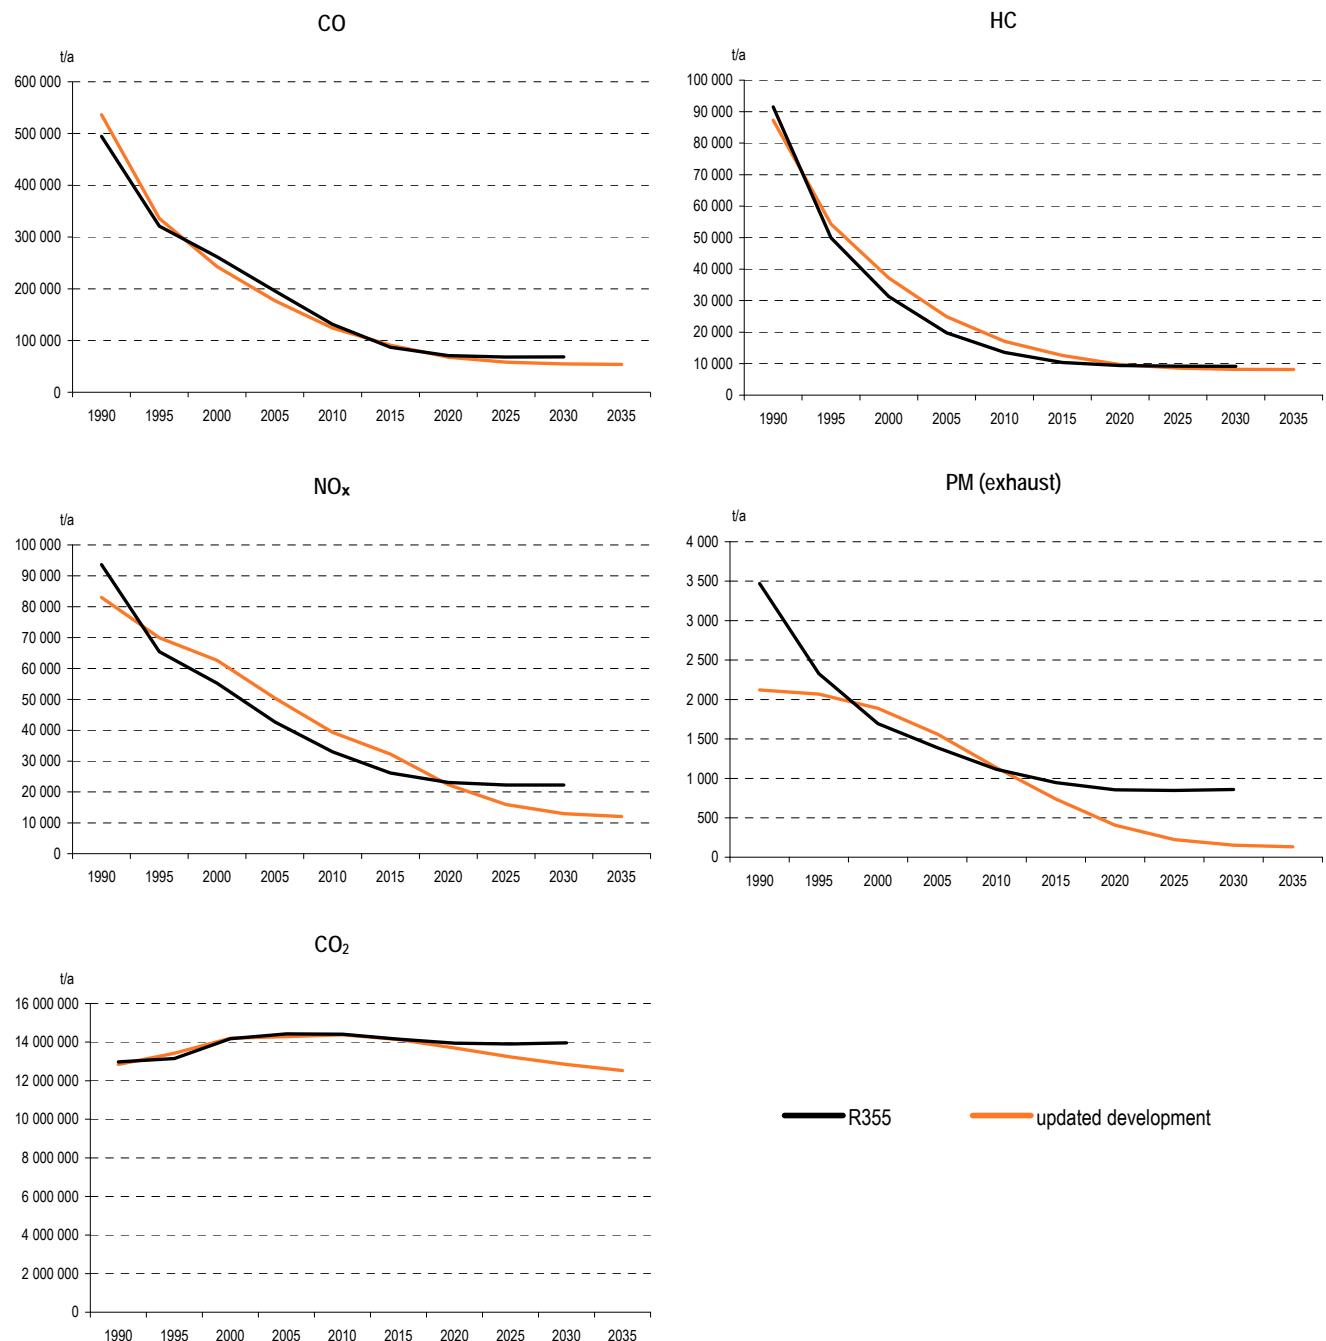

Fig. A > Emission trends by vehicle category, 1990 to 2035

Fig. B > Comparison of updated emission trends with figures from the previous SAEFL Report 355

1 > Introduction

Measuring and documenting air pollutant emissions from road transport has become something of a tradition in Switzerland: the first SAEFL report (no. 55) on this topic dates back to the mid-1980s (SAEFL 1986), and relied largely on specialised literature. However, a variety of gaps in knowledge were subsequently identified, and for this reason the exhaust behaviour of motorised road vehicles was studied in greater depth in a comprehensive research project that was initiated in the first half of the 1990s together with Germany and Austria. At the same time, pollutant emissions from road traffic in Switzerland were calculated for the period from 1950 to 2010. The findings from this project were documented at the end of 1995 in SAEFL report no. 255 ("Pollutant emissions from road transport, 1950–2010") (SAEFL 1995). In addition, the emission factors were summarised and published as a special electronic handbook (INFRAS 1995, HBEFA Version 1.1) intended to serve as a tool for a variety of applications such as emission inventories, environmental impact assessments, etc. In the meantime, various background conditions have changed. In particular, European (and subsequently Swiss) legislation governing exhaust emissions has undergone further development and new emission standards have been set. The emission factors handbook (HBEFA) has therefore been constantly updated. Version 1.2 was published in spring 1999 (CD-ROM, INFRAS 1999), and SAEFL Report 355 was updated at the same time (SAEFL 2000, Supplement). Version 2.1. of the handbook was published in 2004, together with an update of the emission calculations for road transport in Switzerland (SAEFL Report 355 2004). Since that time, activities have been internationally co-ordinated to an increasing extent. The co-operation under the title "D-A-CH" underwent constant expansion and was subsequently renamed "D-A-CH+NL+S+" after representatives from the Netherlands, Sweden, Norway and France became involved in the various activities. At the same time, two international projects (COST 346 and ARTEMIS, an EU project within the scope of the Fifth Framework Programme) were brought to completion. The former "D-A-CH-NL-S+" group was renamed "ERMES" (European Research on Mobile Emission Sources) and as of 2010 is being co-ordinated by the Joint Research Centre of the EU Commission.

In February 2010, Version 3.1 of the emission factors handbook was published on the Internet (www.hbefa.net). This version contains emission factors based on new measurements. The programme was fundamentally reviewed, even though from the point of view of users the functionalities of the handbook itself remained essentially the same. In view of the increasingly international orientation, the "traffic situations" were redefined and standardised. A variety of new approaches were also added, e.g. for measuring cold-start influences and evaporation emissions. In addition to emission-related data for Germany, Austria and Switzerland, HBEFA Version 3.1 now includes data for Sweden and Norway, and data for France will be added in the near future.

This report explains the updated calculation methodology, documents the emission trends in the area of road transport in Switzerland, and reflects changes in both emis-

sion levels and traffic data. The adjustments of emission factors are only reiterated briefly here, since they are explained in detail in the above-cited handbook HBEFA 3.1 (INFRAS 2010). Since the various changes also have retrospective effects, the time frame has been completely recalculated from 1990 onwards, and has also been extended to 2035 (in line with the time frame of the energy perspectives of the federal government).

The structure of this report is similar to that of Report 355. Where no notable changes have been made, sections have been directly adopted from the previous report.

The structure of the report is as follows:

- > Chapter 2 deals briefly with the main changes in emission factors.
- > Chapter 3 deals with the traffic data on which the emission calculations are based.
- > Chapter 4 presents the emission trends and compares these findings with the emission estimates dating from 2004.

2 > Emission fundamentals

2.1 Methodology

The calculations of emissions from road transport are largely based on two data sets: traffic activity (description of traffic volume) and emission factors (specific pollutant emissions, for example in grams per vehicle kilometre). There are different types of emissions in the road transport sector:

- > *Emissions from vehicles with engines in hot operating condition*: these depend on driving behaviour (e.g. speed, dynamics), but also on various other factors such as the gradient. The corresponding emission factors are expressed in grams per vehicle kilometre.
- > *Cold-start emissions*: the level of emissions when a (cold) engine is started up is higher than when it is in hot operating condition. For the purpose of calculating emissions, the difference between the total emission level upon start-up (cold engine) and the emission level in operating condition is taken into account in the form of a cold-start excess.¹ The corresponding emission factors are expressed in grams per start-up (g/start).
- > *Evaporation emissions*: petrol-driven vehicles lose a certain amount of fuel through evaporation. This process only results in HC emissions. In the case of diesel vehicles, evaporation losses are negligible, since diesel fuel has a higher evaporation temperature than petrol. A distinction is made between three types of evaporation according to their source:
 - *Emissions due to diurnal emissions*: evaporation losses from a vehicle with its engine switched off, caused by changing ambient temperatures (fluctuations between daytime and nighttime temperatures), expressed in grams per vehicle and day.
 - *Evaporation after switching off a warm/hot soak*: emissions that result due to the temperature fluctuations when a hot or warm (after being driven for a short stretch) engine cools down, expressed in grams per journey.
 - *Running losses*: evaporation losses while the vehicle is in motion, relevant at high ambient temperatures, expressed in grams per vehicle kilometre.

Thus for the calculation of emissions, two data sets are required, both of which have to be processed according to the degree of differentiation outlined above: on the one hand, the emission factors (in grams per vehicle kilometre, grams per start, grams per stop, grams per vehicle and day), and on the other hand the traffic activities in the form of mileage figures (vehicle kilometres per annum) for calculating the emissions from vehicles with engines in hot operating condition, plus traffic activities in the form of

¹ HBEFA3.1 provides such figures only for passenger cars and light commercial vehicles

the number of starts (for cold-start excess emissions) and stops (for evaporation emissions after switching off when warm/hot), and vehicle stock (for diurnal evaporation emissions).

The vehicles are divided into six categories for emissions calculation purposes, with the following designations:²

- > Passenger cars (PC) – Cars, including heavy models < 3.5 t
- > Light commercial vehicles (LCV) – Light commercial veh. and minibuses < 3.5 t
- Heavy goods vehicles (HGV)
 - Rigid trucks > 3.5 t
 - Trucks and trailers > 3.5 t
 - Articulated trucks > 3.5 t
- > Coaches – Coaches > 3.5 t
- > Urban buses – Urban buses > 3.5 t
- > Motorcycles (MC) – Motorcycles, including mopeds

Combustion engines produce a large number of pollutants. In this report, those pollutants and components have been calculated wherever acceptable data sources exist, either from reliable and in many cases specific measurement programmes (group 1), or from supplementary measurement programmes and/or literature (group 2):

- > Group 1:
 - CO carbon monoxide
 - HC hydrocarbons (total HC)
 - NO_x nitrogen oxides
 - PM particulate matter (exhaust)
 - MF Fuel consumption
 - CO₂ carbon dioxide (calculated on the basis of fuel consumption)
- > Group 2:
 - Pb lead
 - SO₂ sulphur dioxide
 - CH₄ methane, derived from total HC
 - NMHC non-methane HC, derived from total HC
 - Benzene derived from total HC
 - Toluol derived from total HC
 - Xylol derived from total HC
 - NH₃ ammonia
 - N₂O nitrous oxide
 - NO₂ nitrogen dioxide

² The term «light duty vehicle» encompasses passenger cars and light commercial vehicles, while «heavy duty vehicle» refers to heavy goods vehicles, coaches and urban buses.

2.2

Emission factors

The methodology for calculating emissions has remained essentially unchanged compared with Report 355 (FOEN 2004). The emission factors that have been used in this report are based on HBEFA Version 3.1 (2010), which is similar in outline to the previous version (2.1) which was used for Report 355. Nonetheless, the new HBEFA version may be regarded as a remake rather than an update. The main reason for this is that, in view of the increasing international orientation of the handbook, the traffic situations for which the most important emission factors are presented have been redefined. In practice, this means that all emission factors had to be recalculated, including retroactively. Previously, individual measurements for certain driving patterns were directly adopted as emission factors, but now these figures initially had to be transferred via appropriate calculation models to the redefined traffic situations. This resulted in certain deviations, even if the emission level does not change to any notable extent. This also applies to emission data for the past. In addition, the results of new measurements have also been taken into account. As before, wherever measurements are lacking – in particular for future vehicle concepts – the emission factors have been estimated on the basis of reduction rates according to the current legislation on the development of emission standards (cf. Annex A1). The following changes were taken into account for calculating emission levels (cf. report HBEFA 3.1, INFRAS 2010, and www.hbefa.net):

- New emission factors are now also available for emission categories Euro-5/V and Euro-6/VI³. In addition, some vehicle groups have been differentiated in greater detail (e.g. with/without particle filter, SCR/EGR).⁴ Otherwise the definitions of vehicle segments (size categories, Euro categories of emission standards, etc.) are largely unchanged.
- The new depiction of traffic situations groups these on the basis of 4 dimensions: type of region (rural/urban), 5 road categories, speed limit and 4 traffic conditions. This means that the number of emission factors is significantly higher (276). Each traffic situation is associated with a typical driving pattern in the form of a speed progression per second.
- Emission factors of passenger cars (PC):
 - The emission factors for passenger cars have been fully revised. The new data are based on the emission model (PHEM) developed by the Technical University of Graz, which was already used for calculating the emission factors of the heavy duty vehicles in HBEFA Version 2.1. For the calibration of this model, modal emission measurements were used (in seconds) up to Euro-4. For HBEFA 3.1, the compilation of emission recordings of a large number of European laboratories initiated in the ARTEMIS project was continued.

³ Explanation of usage: Arabic numerals are used for emission categories for light motor vehicles (cars, utility vehicles), while Roman numerals are used for designating emission categories for heavy motor vehicles.

⁴ SCR = selective catalytic reduction; EGR = exhaust gas recirculation.

- The emission factors for future vehicle concepts (Euro-5, Euro-6) were estimated on the basis of future legislation.
 - The cold-start emission factors (as before, defined as cold-start excess emissions) were fully revised and are based on a new proposal by EMPA.
 - A new concept was developed for evaporation emissions. The approach was adopted from COPERT IV, and calculations are now based on country-specific input parameters.
- > Emission factors of light commercial vehicles (LCV)
- Here, too, the emission factors were completely revised, and the PHEM model of TU Graz was again used. However, the empirical data base is somewhat limited for the purpose of very detailed differentiation, since in general only very few vehicles are measured in real operation.
- > Emission factors of heavy goods vehicles (HGV)
- As was the case with HBEFA 2.1, the emission factors for heavy goods vehicles and buses were calculated using the PHEM model of TU Graz. However, the number of measurements was significantly increased thanks to measurement campaigns and activities within the scope of international projects such as COST Action 349, ARTEMIS and PARTICULATES.
 - For the purpose of emission calculations, practically the same range of vehicle segments was available (i.e. same weight categories) as before. However, the concepts were extended to Euro VI, and assumptions had to be made for Euro-V and Euro-VI since only very few empirical recordings were available. In two categories (Euro-IV and Euro-V), a differentiation was also made between technology concepts (i.e. SCR and EGR).
- > Emission factors of motorcycles (MC)
- The model for producing emission factors was adapted in line with the model for passenger cars in order to additionally take into account acceleration effects. The database was also expanded, and emission measurements from Germany (ARTEMIS project) were included.
- > New pollutants
- Emissions are now also calculated for NO₂ (“direct emissions”) and particle number. PM (particle mass) emissions for petrol passenger cars (particle mass) are now based on results from the PHEM model.
- > Other changes
- Forecasts regarding fuel consumption and CO₂ emissions now take account of the fact that vehicles are generally becoming more efficient. In addition, country-specific reduction rates are defined on the basis of CO₂ monitoring data for new vehicles (in Switzerland, in line with the evaluations of fuel consumption of new vehicles carried out by “auto-schweiz” on behalf of the Swiss Federal Office of Energy (SFOE), e.g. auto-schweiz 2010).
 - CO₂ emission factors are now shown in a differentiated manner, with a distinction being made between “CO₂ total” and “CO₂ reported” (i.e. in the “CO₂ reported”

figure only the fossil-related CO₂ component is taken into account; additives of biofuels are not included in the calculation).

- For air-conditioning systems, a new calculation method was applied that is based on measurements and a proposal by EMPA.
- Emission factors of N₂O and NH₃ are based on new data from COPERT IV.
- Emissions from vehicles (passenger cars, buses) powered by compressed natural gas (CNG) are now taken into account in a differentiated manner.

3 > Traffic fundamentals

3.1

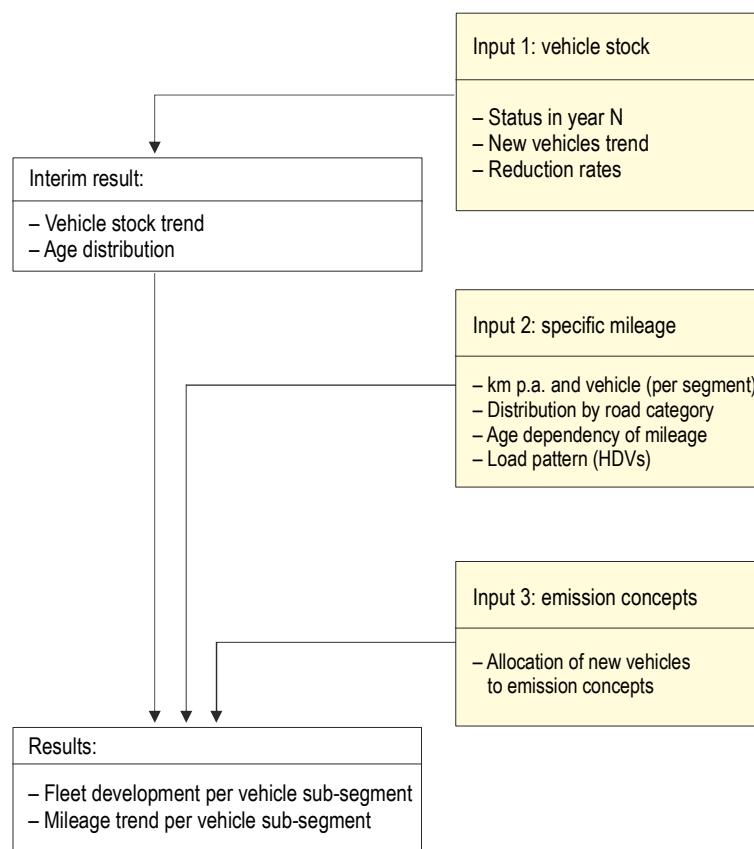

Methodology

As already explained in chapter 2.1, traffic volumes have to be processed in various forms in order to be able to calculate the different emission types, i.e. mileages (vehicle kilometres) have to be calculated, as well as start-up and stop processes (for calculating cold-start and evaporation emissions), and vehicle stock (for evaporation emissions). These have to be differentiated by vehicle category (cf. chapter 2.1). But emission factors inevitably also take account of other technological differences, e.g. type of fuel (petrol/diesel, alternative fuels), different size categories (weight or cubic capacity) and especially emission levels, i.e. the different emission standards that vehicles have to meet depending on their year of manufacture. It is therefore necessary to split up all traffic volumes according to these differentiations, in order to correctly calculate the respective emissions.

The data from various sources have to be combined. Most of the necessary model components for this purpose were adopted from earlier studies (SAEFL 1995, SAEFL 2000, SAEFL 2004) and adapted to the latest criteria (e.g. statistical data where available up to reference year 2008). The overall traffic volume is calculated on a bottom-up basis, in accordance with the following formula:

$$\text{Mileage (per annum)} = \text{vehicle stock} * \text{specific mileage (per annum and vehicle)}$$

On the one hand the statistics concerning vehicle-km driven covered in the past years can thus be reproduced (and calibrated to the data of the Swiss Federal Statistical Office), while on the other hand it is possible to calculate the future trend with respect to total mileage using assumptions concerning the vehicle stock and specific mileage in a consistent manner. In addition, it is possible to comprehensibly model the distribution of new technologies in the vehicle stock and mileage components. Thus traffic composition and mileage trend can be determined in the same model and with the same procedure (cf. Fig. 1). In the context of the handbook of emission factors, this model was used in order to determine the fleet compositions of all involved countries (Germany, Austria, Switzerland, Sweden, Norway, France).

Fig. 1 > Modelling of fleet and mileage trends and fleet composition

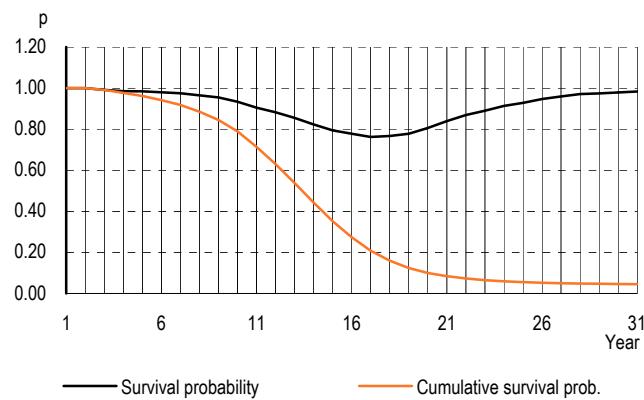

The calculation procedure is essentially divided into three steps:

- > The first step is to model the vehicle stock trend. The past trend is depicted on the basis of statistics of the Federal Vehicle Inspection Office concerning fleet and age distribution. Age distribution is required in order to allocate the vehicles to the corresponding emission concepts in step 3. The future trend is estimated by taking a reference year, i.e. the last year for which statistics exist (in the present case 2008) and making assumptions concerning new registrations and survival probabilities (or equivalent fall-off rates). In this way, the vehicle stock for each future reference year can be depicted as the total of anticipated new registrations and the remaining vehicles from each year of registration – a model that closely corresponds to reality. Here the relatively stable fall-off rates over the course of time form a sound basis for projection. On the other hand, the comparatively uncertain trend concerning new registrations only has a minor influence since the annual volume of new registrations is less than 10 percent of the overall vehicle stock. This procedure is carried out separately for each vehicle category, though additional differentiation is made within these categories, e.g. for passenger cars by diesel/petrol vehicles and three engine capacities (< 1.4 l, 1.4 to 2 l and > 2 l), and now also by CNG-powered vehicles. The illustration below shows an example of a survival probability curve (left) and the trend of the passenger car fleet including age distribution (right).

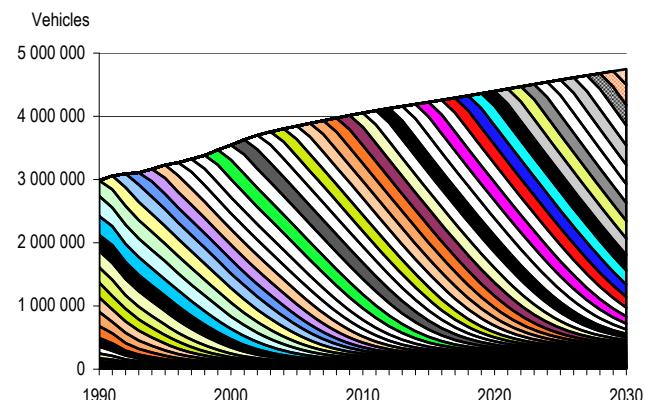

Step 1:
Stock input

Fig. 2 > Depiction of fleet trend (example for passenger cars)

The graph on the left depicts the survival probability curve for passenger cars (status, 2001/2002). The black line shows the probability that a vehicle will still be in circulation in the following year; the orange curve shows the accumulated values (= lifetime function) and indicates the probability that a vehicle will remain in circulation for x years.

The vehicle stock (passenger cars) is shown on the right, including new registrations and gradual elimination of vehicles. With a vertical line in a given reference year it is possible to read off the corresponding age distribution.

The mileage characteristics of the various vehicle categories are entered in the form of a second data set. Firstly the specific mileage for each vehicle category has to be defined (in kilometres per annum and vehicle). The mileage combined with the vehicle stock figure results in the total mileage for each year. At the same time, the mileage is distributed over the three road categories (motorways, rural roads, urban roads).⁵ The various segments⁶ now have different mileage characteristics; for example, diesel passenger cars have a higher mileage than petrol passenger cars, heavy duty vehicles have a higher mileage than light duty vehicles, etc. For this reason, the same inputs are processed segment-specifically (specific mileage p.a., distribution over road categories) in a second step. Since this dual procedure (same inputs at vehicle category level as at segment level) can give rise to inconsistencies, a mathematical adjustment is made in order to ensure that the total figures over all segments are consistent with the mileage figures per vehicle category. Here it is the key figures per vehicle category that are of relevance, since the empirical basis is more reliable than the basis per segment. At the same time it is also possible to reflect segment-specific differences. In addition, the age dependency (per segment) is taken into consideration since as a rule newer vehicles have a higher mileage than older ones. With heavy duty vehicles, two additional inputs are taken into account: figures recorded in the motor vehicle statistics refer to traction vehicles (trucks and tractors). For emission purposes, however, it is overall weights that are relevant, so in addition to rigid trucks, trucks and trailers and articulated trucks have to be included. It is therefore necessary to separate mileage figures for HGVs into solo and articulated vehicles, which is now possible on the basis of empirical data

Step 2:
Depiction of mileage

⁵ In addition, driving behaviour is also specified, i.e. the distribution of traffic volumes over various traffic situations that are characterised by different speed and acceleration patterns. These were fundamentally redefined in HBEFA 3.1, from which they can therefore be directly adopted (cf. INFRAS 2010).

⁶ Here, «segment» refers to a vehicle group (within a vehicle category) with the same fuel type (petrol/diesel) and size (dimensions, cubic capacity) of engine.

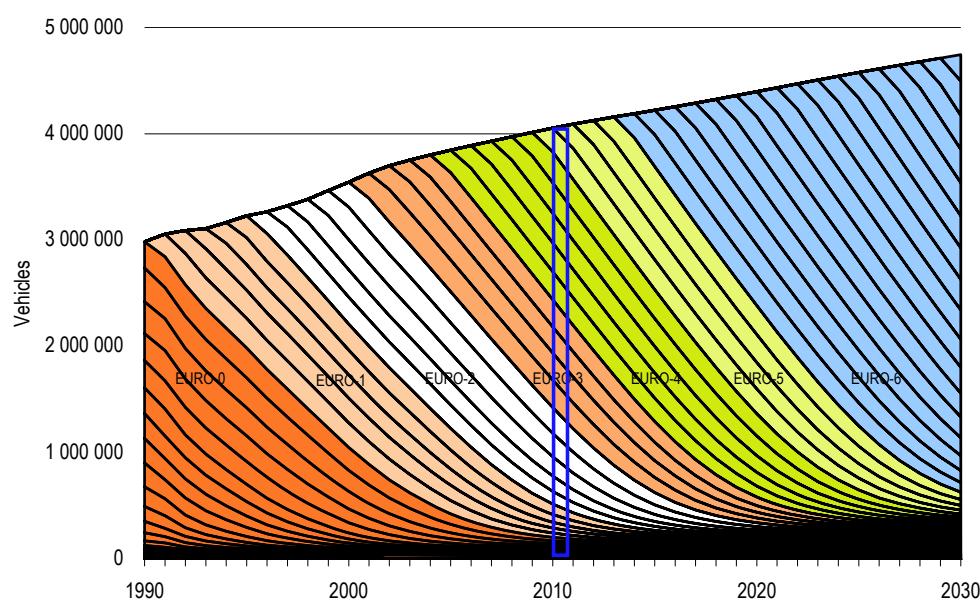

relating to the Swiss distance-related heavy vehicle fee (HVF). For the same reason, the load rate – which is another necessary input for characterising the mileage of heavy goods vehicles – is also relevant.

- The third input data set establishes the link to the emissions side. Here the emission category to which new vehicles from a given year of manufacture are to be allocated is defined for each year. In this way it is possible to estimate the proportions of the various emission categories for all reference years from the combination with the fleet development differentiated by age (cf. Fig. 3). This procedure is carried out at the segment level. At the same time, the corresponding mileage figures per segment are also known, and from these the proportions of the various vehicle sub-segments can be calculated – weighted once by fleet and once by mileage, as required for the calculation of emission factors.

Step 3:
Depiction of emission concepts

Fig. 3 > Development of vehicle stock by emission category (example: passenger cars)

This graph shows the development of the fleet by year of construction. Each segment framed in black represents a group of vehicles with the corresponding year of manufacture, and these are coloured in accordance with their main emission category. The blue rectangle indicates the status as of 2010. The coloured sections inside the rectangle reflect the vehicle stock composition by emission category in 2010.

3.2 Trend in traffic volumes

3.2.1 Mileage

It is not possible to simply measure how the mileage figures develops in Switzerland.⁷ Instead we have to rely on a variety of indicators and surveys. The applied models have to be constantly adapted on the basis of ongoing developments. The figures in this report relating to total mileage are primarily based on publications of the Swiss Federal Statistical Office (FSO 2009); 2008 was taken as reference year. The figures relating to the future trend are based on the transport perspectives of DETEC (ARE 2004, ARE 2006). The respective trends are described briefly below. Please refer to Fig. 4 for an overview in graphic form, and to Annex A2 for a summary of the respective figures.

Until 2008, the data published in FSO 2009 were used.⁸ The mileage figures for passenger cars are only marginally higher versus Report 355 (FOEN 2004). A similar trend to that recorded around five years ago is anticipated for the future. Compared with 2008, the anticipated growth for 2020 and 2035 are 13 percent and 21 percent respectively, i.e. significantly slower than in the past.

The FSO recalculated the mileage figures for light commercial vehicles (including retroactively) following the introduction of the heavy vehicle fee, and adjusted them sharply downwards. For the future, the applicable growth rates are based on the goods transport perspectives and adapted to the lower figures.

For the period since the introduction of the heavy vehicle fee (2001), reliable mileage figures are available in Switzerland for heavy goods vehicles. The FSO retroactively adjusted the figures slightly for the period from 1990 to 2000 versus the data that were available in the previous report. The figures for the current period largely match those that were used at that time. In the same way as for light commercial vehicles, the growth rates are based on the goods transport perspectives and have been adapted to the level for 2008, which means that the mileage figures for heavy goods vehicles are practically identical to those in Report 355.

In absolute terms, the mileage figures for buses are relatively low. According to the FSO, the figures for coaches have increased, and in view of this the initial level on which previous growth rates were based has been adjusted slightly.

In the case of public transport buses, contrary to the predictions in the earlier study a higher growth rate has been assumed in line with the current sharp increase in demand in the area of rail travel, which is expected to persist in the future.

Passenger cars

Light commercial vehicles

Heavy goods vehicles

Buses and coaches

⁷ With the exception of mileage for HGVs: here it is possible to collect practically complete statistics thanks to the introduction of the Swiss distance-related heavy vehicle fee.

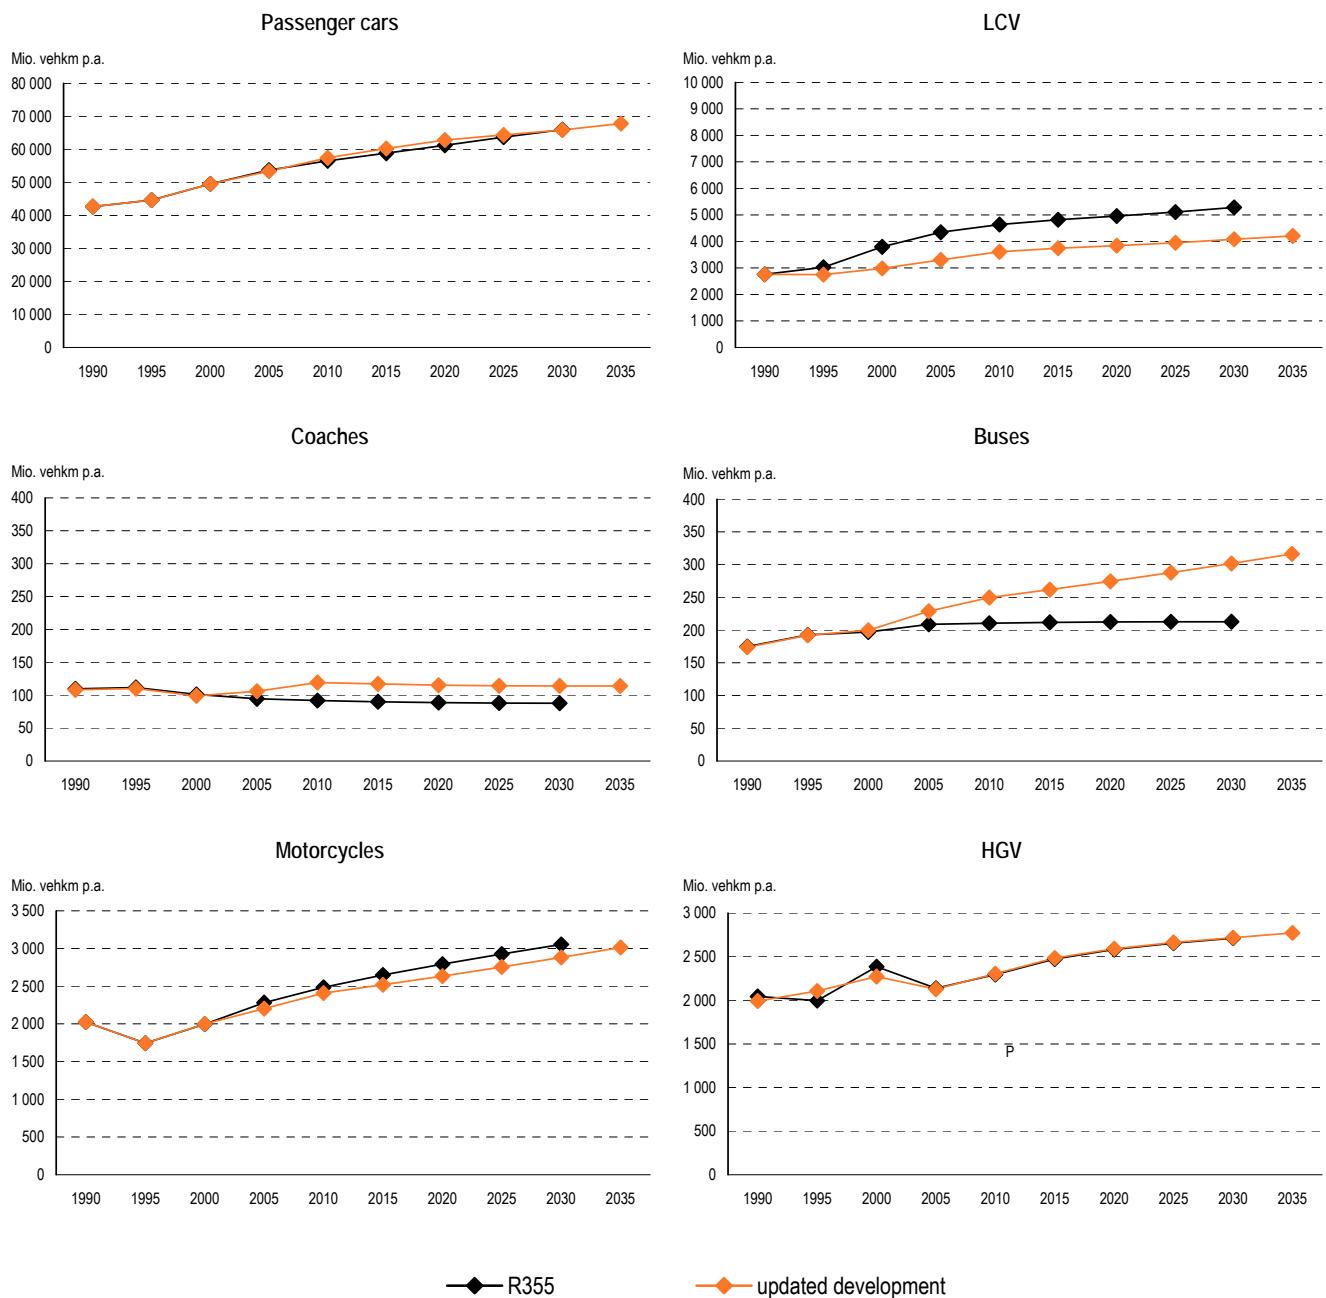

⁸ In 2009, the FSO adjusted the mileage figures for foreign vehicles (and subsequently the total mileage for cars) downwards. This adjustment has not been reflected in the figures in this report since validation with fuel sales was not regarded as sufficient justification for such an adjustment (cf. chapter 4.2).

The mileage figures of motor cycles have increased to a slightly lower extent than was assumed in Report 355. In view of this, the growth rate in this category has been adjusted slightly downwards, and for 2030 is now around 6 percent below the level cited in Report 355.

Motorcycles, scooters, mopeds

Fig. 4 > Mileage trend, 1990 to 2035 (million vehicle kilometres per annum)

Comparison of updated trend (in orange) with results of previous SAEFL "Report 355" (in black).

3.2.2

Vehicle stock, starts and stops

Excess emissions from starts, as well as evaporation emissions, are calculated for passenger cars and light commercial vehicles in addition to hot emissions, and evaporation emissions are also shown for motorcycles. This means that, in addition to the mileage trend, forecasts concerning the development of vehicle stocks as well as the number of start and stop procedures have to be made for the above mentioned vehicle categories.

As we can see from Fig. 1, the fleet development is an integral component of the methodology. This ensures that the fleet trend is consistent with the mileage scenarios. The corresponding data are shown in Annex A2.

The factors relating to the number of starts and stops per day have been redefined on the basis of the 2005 micro traffic census. Here the “stages concept” used in the census was adopted, i.e. each stage is associated with a start. At the same time, the required parameters for cold-start calculations (distribution of mileages and parking times, differentiated by time of day) were calculated in order to place the cold-start model on a firmer footing. It was found that the number of starts per car is around 10 percent lower than previously assumed. For the other vehicle categories (light duty vehicles and motorcycles) the previous bases were used since no newer figures were available.

3.3

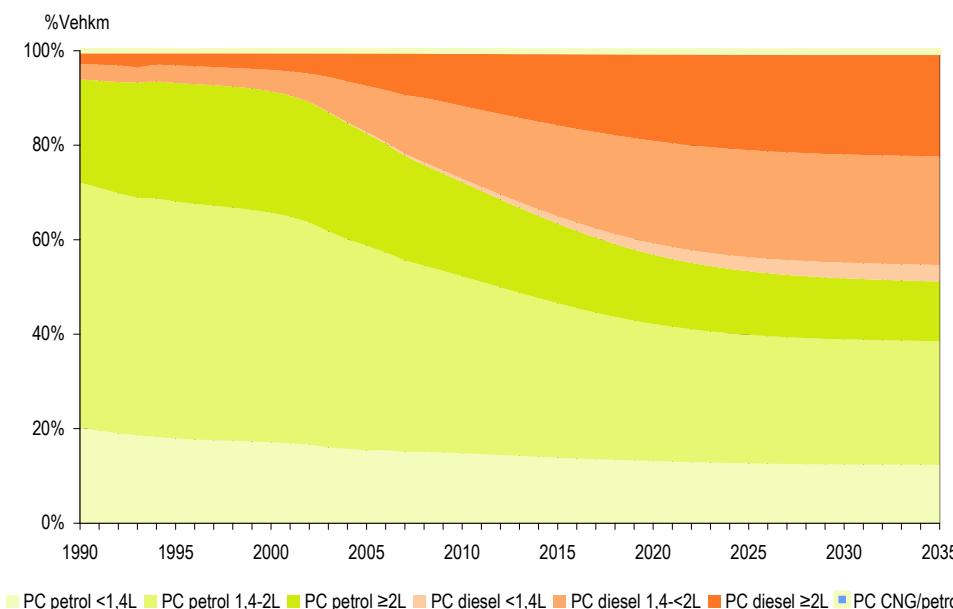

Traffic compositions

This term refers to the composition of the vehicle stock within a given vehicle category, not to the composition of traffic on the road by vehicle category. Data concerning this composition are essential for making emission calculations. Fleet trend and fleet compositions are now integrated components of the model for calculating traffic volumes. The most important assumptions for each vehicle category are outlined below.

The most pronounced change in composition is the sharp increase in the proportion of diesel passenger cars since the end of the 1990s (cf. Fig. 5). In 2009 the proportion of diesel passenger cars among new vehicle registrations was 30 percent (auto-schweiz 2010). A further increase in the proportion of new vehicles to 40 percent is assumed, after which it is expected to stabilise at this level. Since diesel vehicles tend to indicate a high specific mileage, their proportion to the overall mileage is expected to rise more sharply, even if this effect tends to be lessened as the proportion of diesel vehicles increases. In consideration of the fact that the fleet of foreign vehicles that use Switzerland's roads will include a higher number of diesel-powered passenger cars, the proportion of the latter is expected to increase to 48 percent by 2030. This is the basic scenario in which vehicles using alternative fuels are of little significance. The anticipated proportion of CNG-powered passenger cars is 1 percent, while electric cars do not play a role in this scenario.

Passenger cars

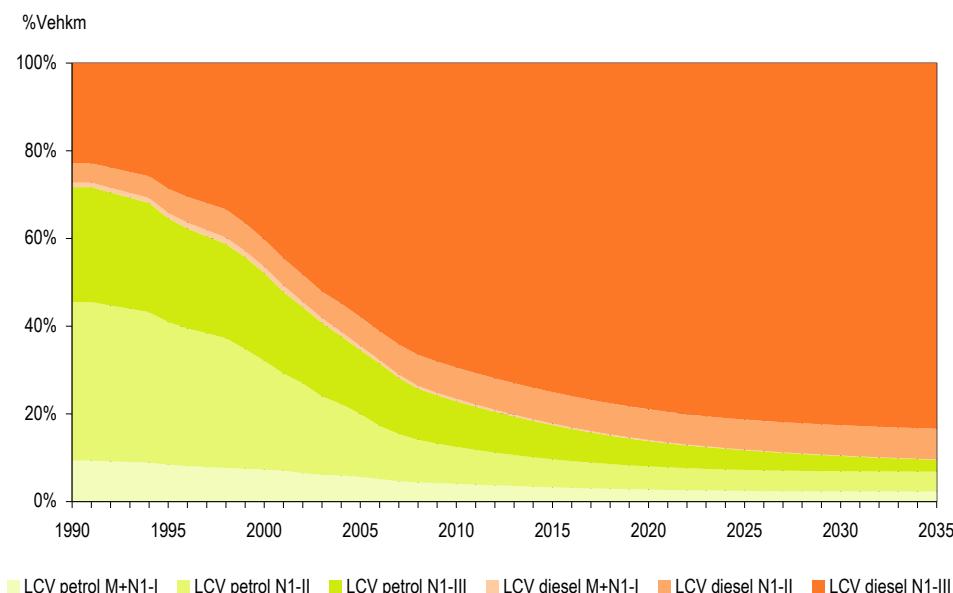

Fig. 5 > Mileage proportions of the various passenger car segments in the period from 1990 to 2035

For light commercial vehicles, a distinction is made by size category as well as by type of fuel. The three categories as defined in legislation on exhaust emissions are M+N1_I/N1_II/N1_III; definition, see Annex A2. The trend towards large diesel-fuelled vehicles also becomes apparent from the mileage proportions (cf. Fig. 6). According to the current assumptions, diesel-fuelled light duty vehicles (category N1-III) will account for approximately 85 percent of the mileage in 2030.

Light commercial vehicles

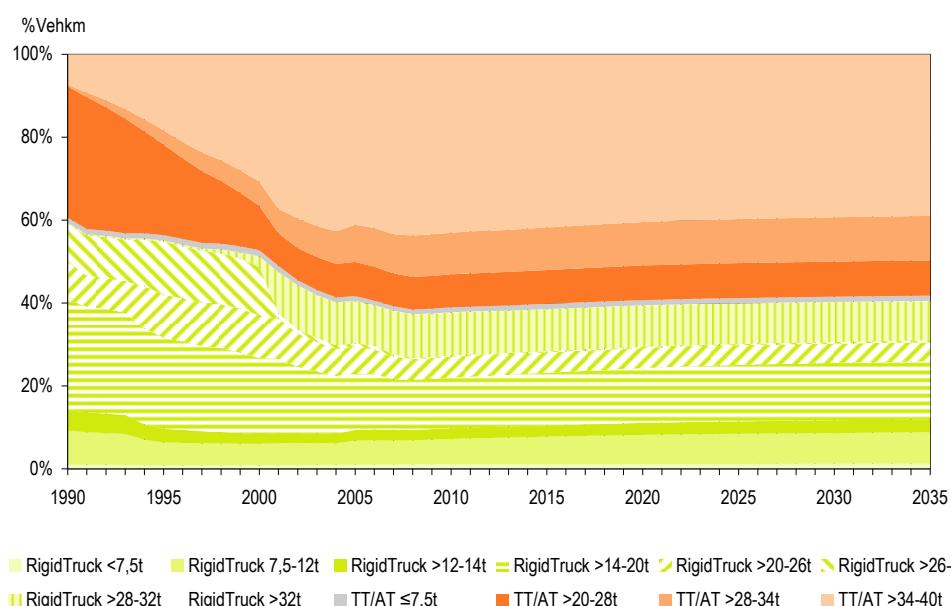

Fig. 6 > Mileage proportions of the various light commercial vehicle segments in the period from 1990 to 2035

The increase in the weight limit for HGVs from 28 to 40 tonnes, and the introduction of the Swiss heavy vehicle fee in 2001, have significantly changed the composition of the HGV fleet. As far as the emission trends are concerned, it is not so much the legally permissible weight as the real vehicle weight that is of relevance. Although a weight limit of 28 tonnes was in effect in Switzerland until 2000, it may be assumed that vehicles with a technical total weight of 40 tonnes were already on Switzerland's roads before that date, but they were usually operated with a correspondingly reduced load. The increase of the weight limit and simultaneous introduction of the HVF in 2001 therefore had impacts at different levels: capacity utilisation rose drastically, and there was an added incentive to buy (large) new vehicles that meet the newest emission standards, since these would be subject to a lower HVF.

Heavy goods vehicles

Fig. 7 > Development of mileage proportions of heavy goods vehicles in the period from 1990 to 2035

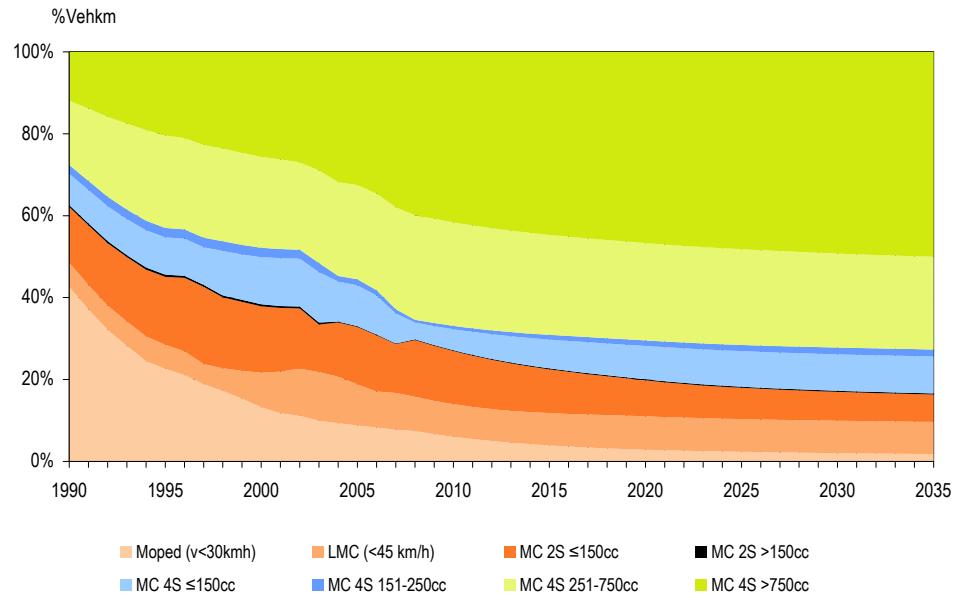

As before, there are two main trends with respect to motorcycles that influence their development (cf. Fig. 8):

- > The proportion of mopeds falls sharply and is to some extent offset by small motorcycles or 2-stroke or 4-stroke motorcycles < 150 cc. Since the service life of these vehicles is relatively short, the fleet stabilises itself comparatively quickly, assuming that new registrations remain constant.
- > There is also a high number of new registrations of large motorcycles. Since their average service life is much longer, the overall fleet is expected to grow over the long term, assuming a constant level of new registrations.

Motorcycles, scooters, mopeds

Fig. 8 > Development of mileage proportions of motor cycles in the period from 1990 to 2035

Moped; LMC: light motorcycle; MC 2S: 2-stroke motorcycle; MC 4S: 4-stroke motorcycle

3.4

Emission concepts

The allocation of emission concepts for specific years of manufacture has been adjusted since Report 355 in that new emission categories (Euro-5/V and Euro-6/VI) have been decided. At the same time, the evaluation of motor vehicle stocks has been updated until 2008 in combination with type approvals.

Fig. 9 > Emission concepts by registration (petrol-driven passenger cars)

Depiction of the introduction of new technological concepts in the area of petrol-driven passenger cars: Euro 4 came onto the market earlier than previously anticipated as the result of promotion measures by some cantons. However, it is also apparent here that this introduction took place on a step-by-step basis, i.e. some new vehicles still meet older standards.

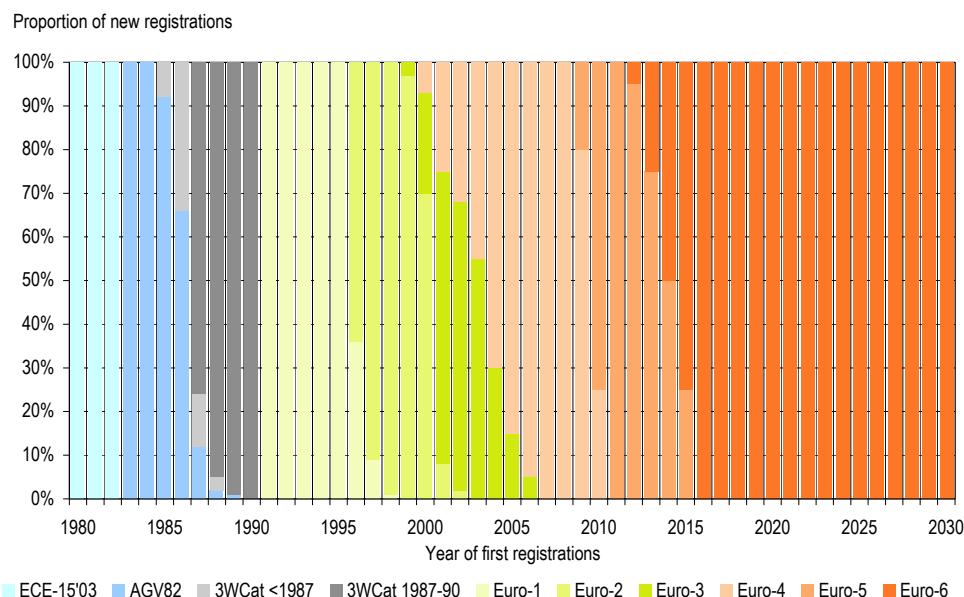

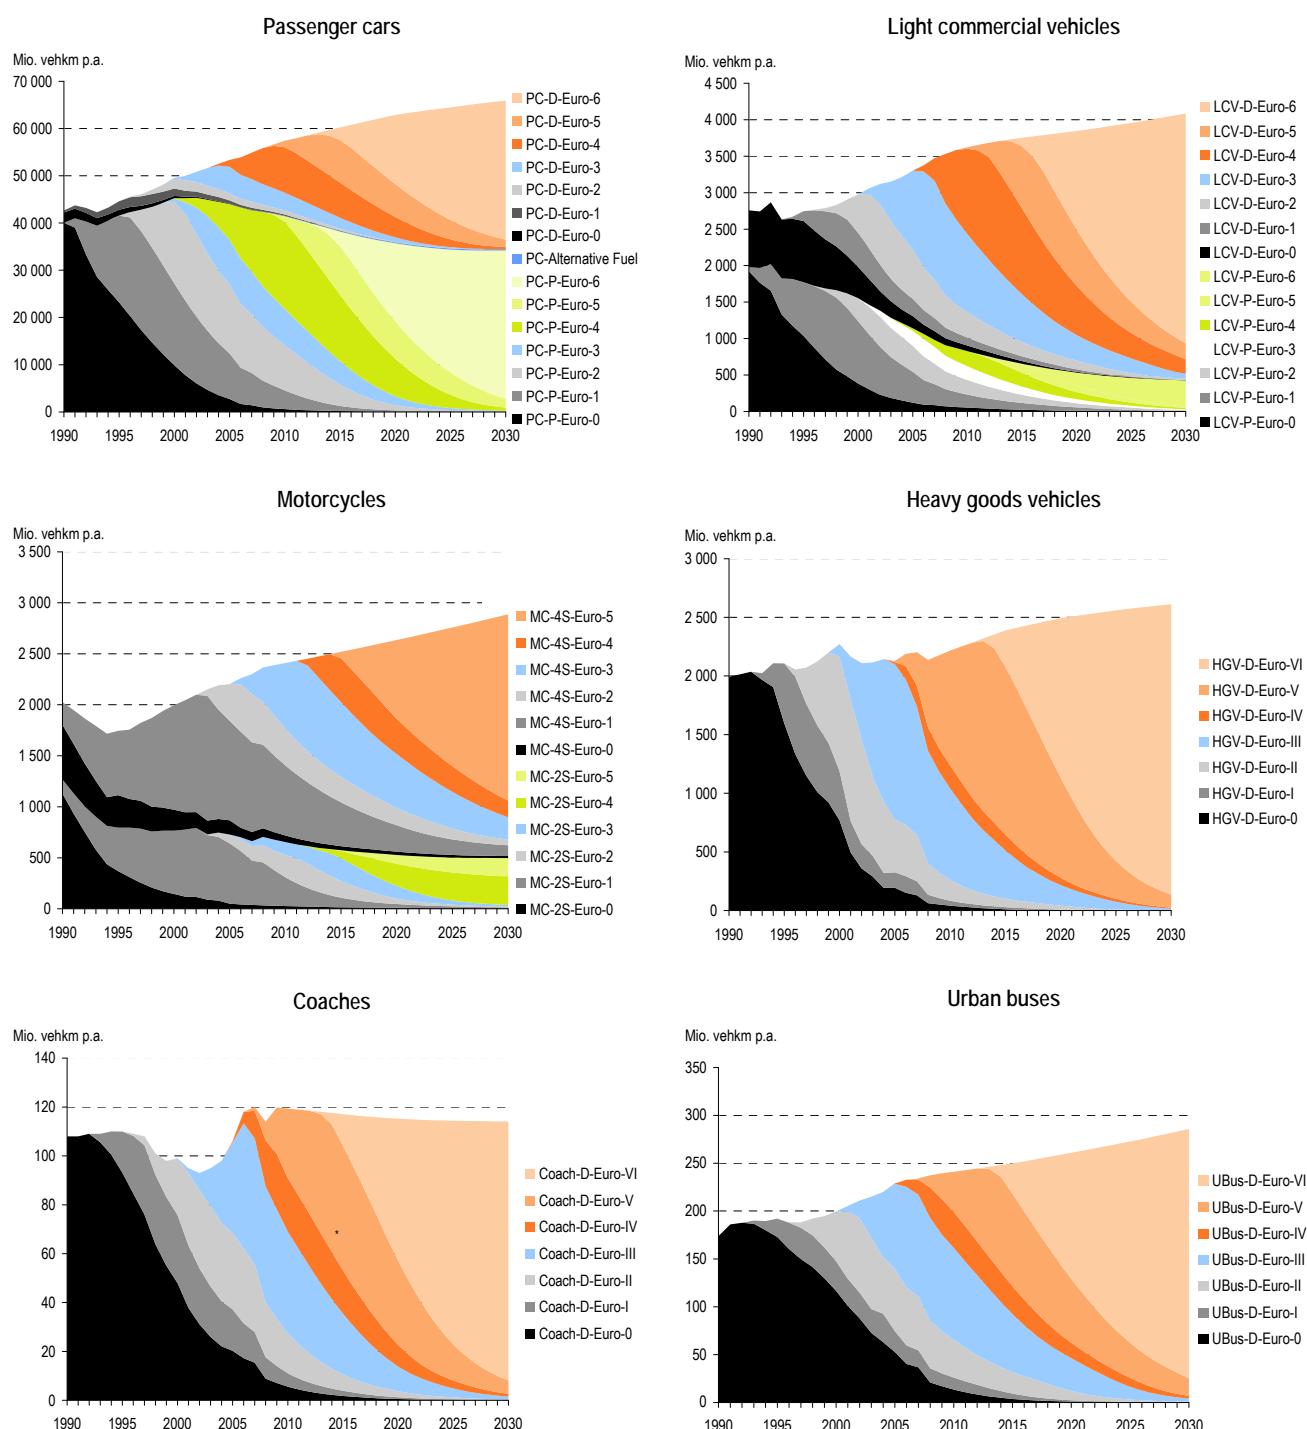

Fig. 10 shows the penetration of emission concepts in the various vehicle categories.

Fig. 10 > Mileage composition by emission concept (in million vehicle kilometres p.a.)

Continual substitution of older technologies by new ones constantly alters the fleet composition or mileage by emission concepts in all vehicle categories.

Figures are reproduced in Annex A3, but are also available in the handbook of emission factors in road transport, version 3.1. (INFRAS 2010)

4 > Emission trends, 1990 to 2035

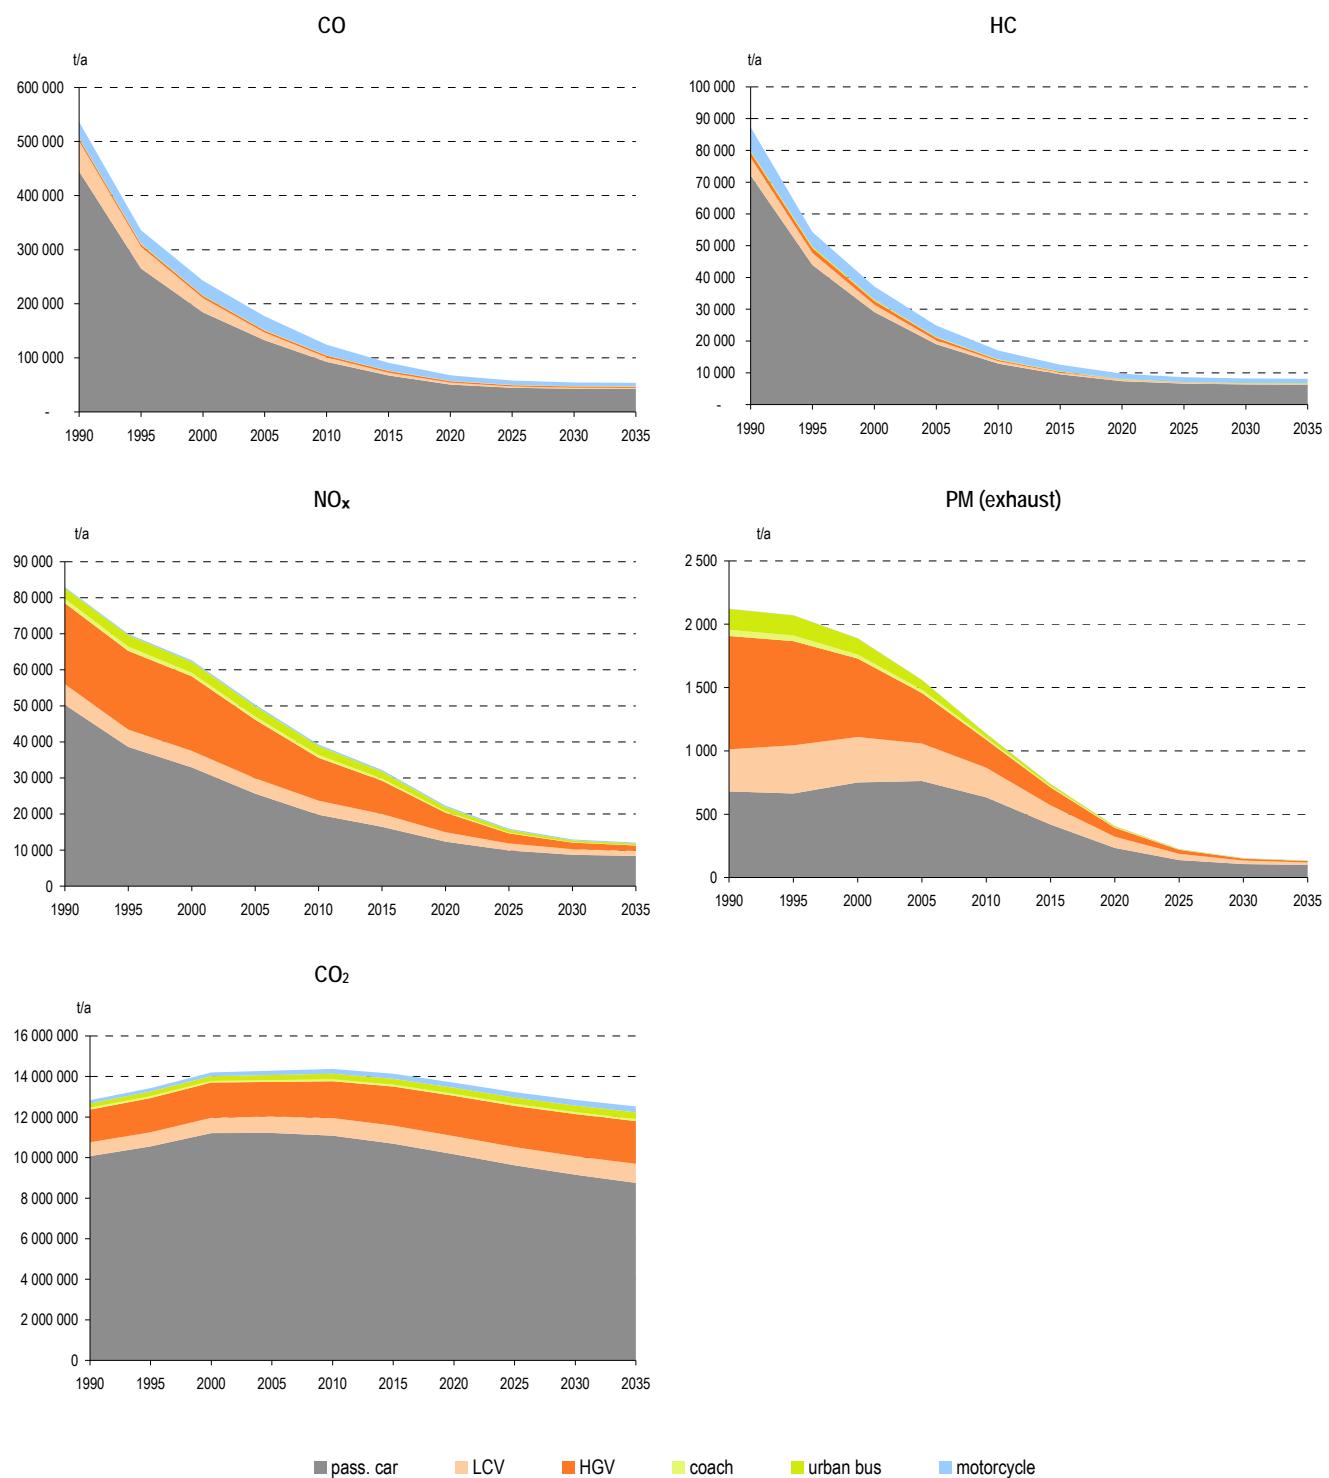

4.1 Overview

4.1.1 Pollutant trends

The following illustrations show the findings for selected pollutants. The figures pertaining to the pollutants shown in the illustrations and other calculated pollutants can be found in Annex A5, and the corresponding emission factors are summarised in Annex A6. The illustration depicts the 1990–2035 time series; the pre-1990 figures are no longer shown (cf. SAEFL 2004). The trend reflects all emission concepts that are currently binding or foreseeable, including Euro-5 and Euro-6 (for light duty vehicles) and Euro-V and Euro-VI (for heavy duty vehicles). For 2-stroke and 4-stroke motorcycles, emission levels Euro-4 (from 2012) and Euro-5 (from 2015), and for motor scooters and mopeds, emission levels Euro-3 (from 2012) and Euro-4 (from 2015) have been assumed.

Fig. 11 shows the emission trends for the period from 1990 to 2035 by vehicle category. The curves confirm the general trends that were stated in Report 355, namely that the “major” reductions have already taken place. The emission level will decline further, but the extent of the reduction will lessen. The reductions in CO and HC, of which passenger cars are the main sources, were especially pronounced. SO₂ and lead are not shown in Fig. 11, but the data in Annex A5 document the direct impacts of improvements in fuel quality. The reductions in NO_x emissions are also clearly visible, but the reduction curve is delayed, primarily due to the increasing proportion of diesel passenger cars. The situation with respect to particle emissions is of particular note in that the increase in diesel passenger cars has partly offset the reduction in HDVs to some extent. PM emissions only reduce significantly with the step-by-step introduction of diesel particle filters. The graph only depicts the trend for exhaust particles; non-exhaust particles are dealt with in chapter 4.2.1.

We can anticipate a noticeable reduction of pollutants despite traffic growth, since technical measures have not yet been exhausted and Euro-5 and Euro-6, respectively Euro-V and Euro-VI, should give rise to further significant reductions.

Fig. 11 > Emission trends by vehicle category

4.1.2

Development of CO₂ emissions

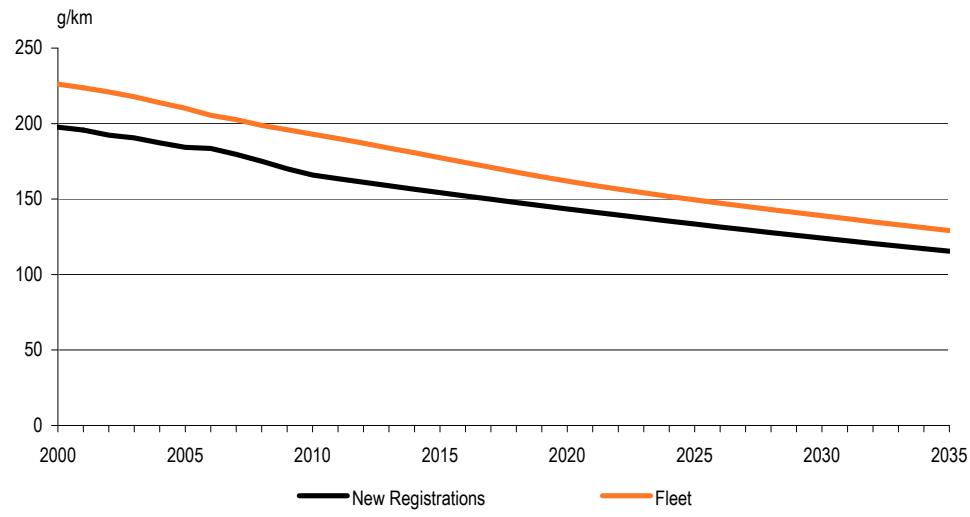

The relatively positive forecast concerning the further reductions of pollutant emissions cannot be equally applied to fuel consumption, and consequently to CO₂ emissions, even if, for example in comparison with Report 355 (issued in 2004), slightly more optimistic predictions apply. While in Report 355 it was still assumed that vehicle-related efficiency gains and traffic growth would more or less offset one another, a more optimistic efficiency trend is now assumed for passenger cars in that the previous average reduction of fuel consumption by around 1.5 percent per annum (i.e. average for the period from 2000 to 2008) will continue for the entire period up to 2035. This reflects a case of “business as usual”. With these assumptions, the mean level of CO₂ emissions (standard consumption) from new vehicles of 175 g CO₂/km in 2008 is projected to fall to 147 g CO₂/km in 2020, and to 127 g CO₂/km in 2030. In terms of mean fleet consumption (g CO₂/km), this represents a reduction by 14 percent in 2020 versus 2010, with 9 percent traffic growth (passenger car kilometres), so that on balance the CO₂ emissions from passenger cars fall by 5 percent. The respective figures for 2030 are minus 25 percent (mean fleet consumption) with 15 percent traffic growth versus 2010 (on balance, minus 10 percent CO₂), and for 2035 are minus 30 percent (mean fleet consumption) with 18 percent traffic growth versus 2010 (on balance, minus 12 percent CO₂). For the other vehicle categories, in this “business as usual” case it is assumed that reduction rates will remain largely unchanged versus the previous report. With these assumptions, after reaching a peak of 14.4 million tonnes in 2010, CO₂ emissions from road traffic fall to around 12.8 million tonnes in 2030, which is roughly equivalent to the level recorded in 1990. This means that CO₂ emissions will decline.

Efforts are now being made to sharply reduce the specific fuel consumption of new vehicles. The EU, for example, is targeting a level of 130 g CO₂/km for passenger cars in 2015 (for the average for all new vehicles), and a level of 95 g CO₂/km as of 2020. The EU is also considering the possibility of introducing target levels for goods vehicles. In October 2009, for example, the EU Commission proposed a target level of 175 g CO₂/km as of 2016, and a long-term target (2020) of 135 g CO₂/km. Switzerland is also making similar efforts. In its message concerning the people’s initiative calling for more “people-friendly” vehicles, and regarding a proposed amendment to the Swiss Federal CO₂ Act (20 January 2010), the Federal Council proposed the introduction of emission regulations for passenger cars with effect from 2012, along the lines of the EU regulations. This would inevitably require continual sharp reductions for new vehicles (i.e. efficiency gains of around 4 percent per annum).⁹ This would mean that the level of emissions would also fall considerably more sharply than depicted in Fig. 11. However, calculations for other scenarios were not made within the scope of this study.

⁹ The average reduction of fuel consumption of new vehicles was around 1.5 percent p.a. in the period from 2000 to 2008, though in the last 2 years in that period (i.e. 2007/2008 and 2008/2009), the reduction was around 4% in each case.

Fig. 12 > Specific CO₂ emissions (passenger cars)

This graph shows the development of specific CO₂ emissions for new passenger cars (up to 2008 according to "auto-schweiz" based on type approval data) and for a "business as usual" case from 2009. Also depicted is the development of the mean CO₂ emissions level of the fleet, which includes real traffic conditions.

4.1.3

CO₂ emissions by territorial and sales principle

In this report, CO₂ emissions have been calculated on the basis of the territorial principle. In other words, the data refer to emissions resulting from vehicles travelling on Switzerland's road network. But for the CO₂ Act, as well as for the greenhouse gas inventory in accordance with the Kyoto Protocol, emissions have to be shown in accordance with the "sales" principle. Here the volume has to be indicated that corresponds to the quantity of fuel that is sold in Switzerland within a year. This is a clearly verifiable figure. The corresponding energy volumes are reported in the overall statistics of the Swiss Federal Office of Energy. In the table below, CO₂ emissions are shown in accordance with both principles. Sales figures have been reduced by the proportion attributable to off-road machines (construction, agricultural and forestry machinery, ships and boats, railway shunting locomotives, etc.) in order to record the sales of fuel for use on the road network. Apart from statistical uncertainties during calculation, the difference is largely attributable to the practice of fuel tourism. This occurs because there is a significant difference between the prices of fuels in Switzerland and those in its neighbouring countries. Petrol has been cheaper in Switzerland for many years, and there is thus an incentive to buy fuel here, even if most of it is used for travelling on roads abroad. In the case of diesel, the reverse situation applied for many years. Due to exchange rate trends, however, diesel too has been cheaper at times. A recently published study (INFRAS/CEPE 2010) estimates the proportions of fuel tourism as approximately 10 percent for petrol and 3 percent for diesel. This means that CO₂ emissions recorded on the basis of the sales principle are higher than those recorded on the basis of the territorial principle. Tab. 1 below presents a comparison between the two sets of figures.

**Tab. 1 > Comparison of CO₂ emissions by territorial and sales principle in 2008
[million tonnes per annum]**

Year	Territorial principle	Sales principle (excluding off-road proportion)
2008	14.32	16.19

4.2**Comparison with the previous report SAEFL 355****4.2.1****Emission trends**

The updated emission trends are only slightly different from the previously published calculations (cf. Fig. 13). The most striking change concerns particles. But this difference is mainly attributable to the use of a different calculation methodology. In Report 355, the estimated PM emissions from older heavy duty vehicles that were not yet regulated were considerably higher. Furthermore, it is apparent that, after 2020, the curves fall more sharply than anticipated in 2004 in Report 355. This is attributable to the inclusion of the new Euro-5/V and Euro-6/VI concepts. It is also apparent that the reduction of pollutants was considerably slower than originally estimated a few years ago. This especially applies to NO_x emissions, for which the estimated 2010 level has been adjusted upwards by approximately 20 percent. This is partly attributable to the increase in the proportion of diesel-powered passenger cars, but also to the fact that the estimate of emission factors for passenger cars has been increased. This applies to older petrol cars (Euro-1, Euro-2), but above all to Euro-3 and Euro-4 diesel cars. While Report 355 based its (optimistic) expectations on the trend in limit values, measurements now show that NO_x emissions from Euro-3 and Euro-4 diesel passenger cars in real operation are significantly higher than originally anticipated.

The differences with respect to HC and CO emissions are only slight, since compensatory effects were observed: in particular, cold-start emission factors have increased, but recent traffic censuses (e.g. 2005 micro traffic census) have shown that the number of start procedures has fallen (by around 10 percent from 2.68 to 2.4 starts per day and vehicle).

With respect to particles (cf. Fig. 14), PM non-exhaust emission factors are unchanged versus Report 355. Since the relevant traffic volumes are the same or very similar, changes in PM non-exhaust emissions are fairly insignificant. The changes relating to PM exhaust emissions are greater, however. PM emissions from older vehicles (light duty vehicles and motorcycles in addition to heavy duty vehicles) have been reduced, so that levels for the 1990s are correspondingly lower. The current level of emissions is very similar to that depicted in Report 355. Exhaust particle emissions are projected to decline more sharply over the long term than previously forecast, since the level of specific emissions (in g/km or g/kWh) should be significantly reduced following the introduction of Euro-5/V and Euro-6/VI.

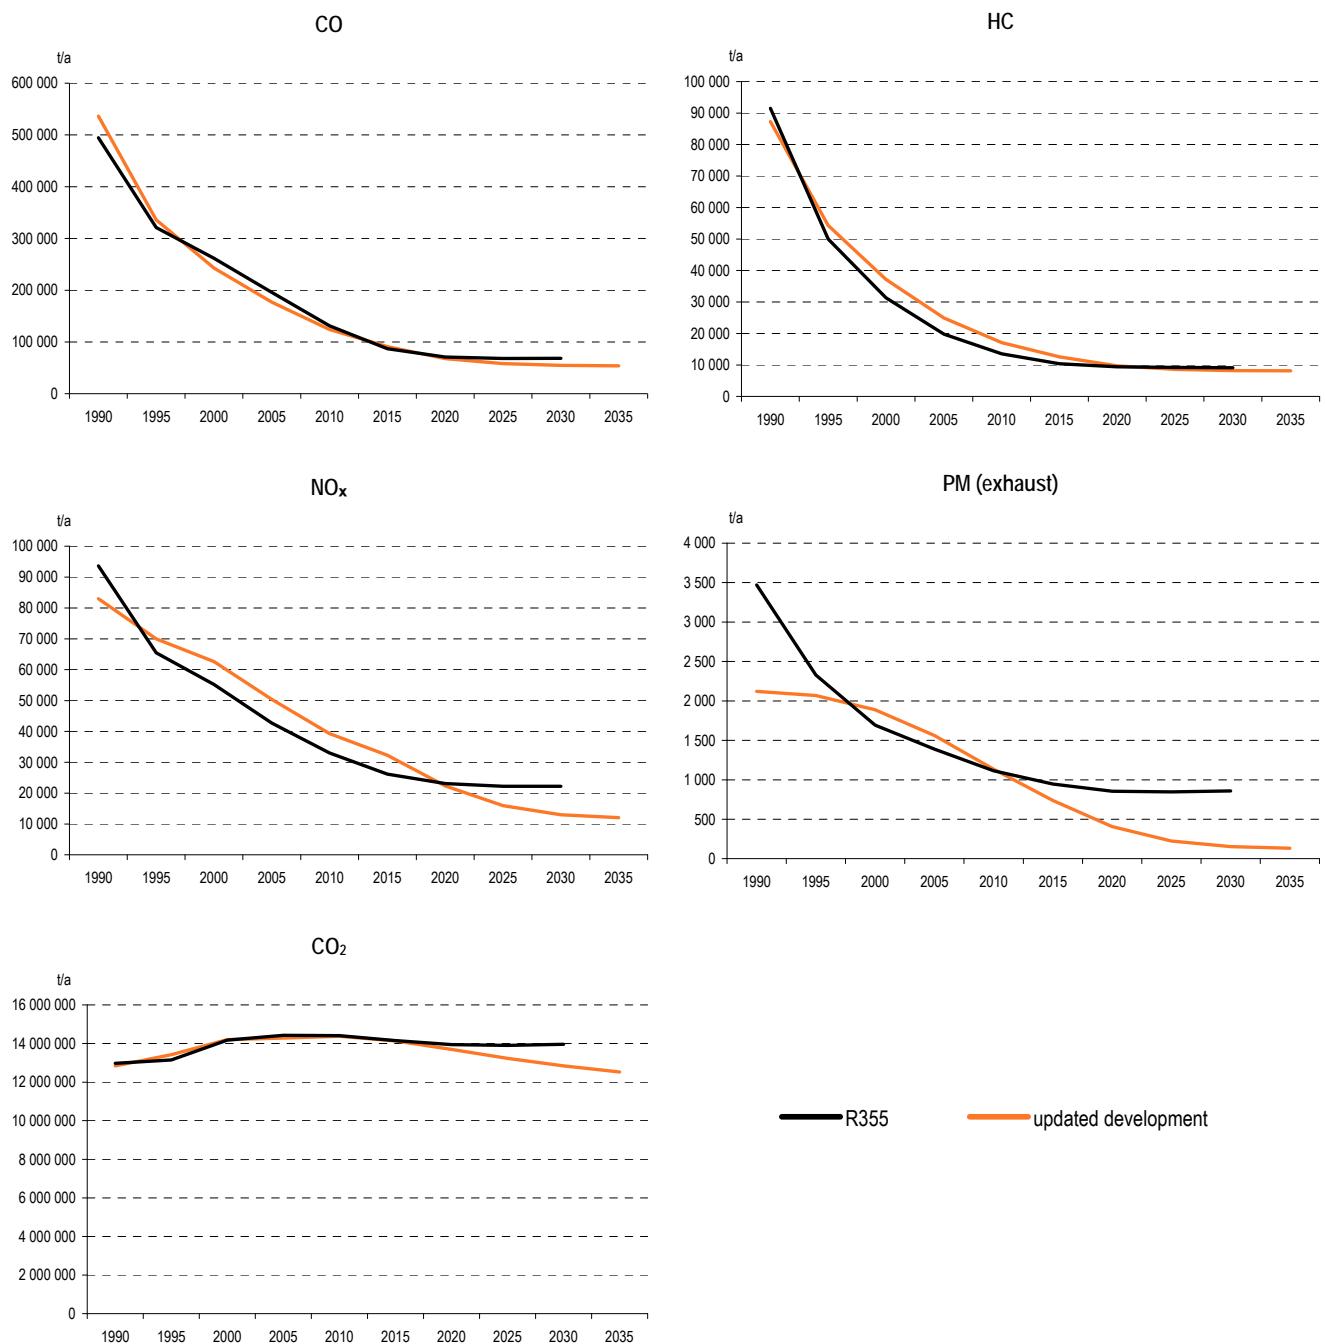

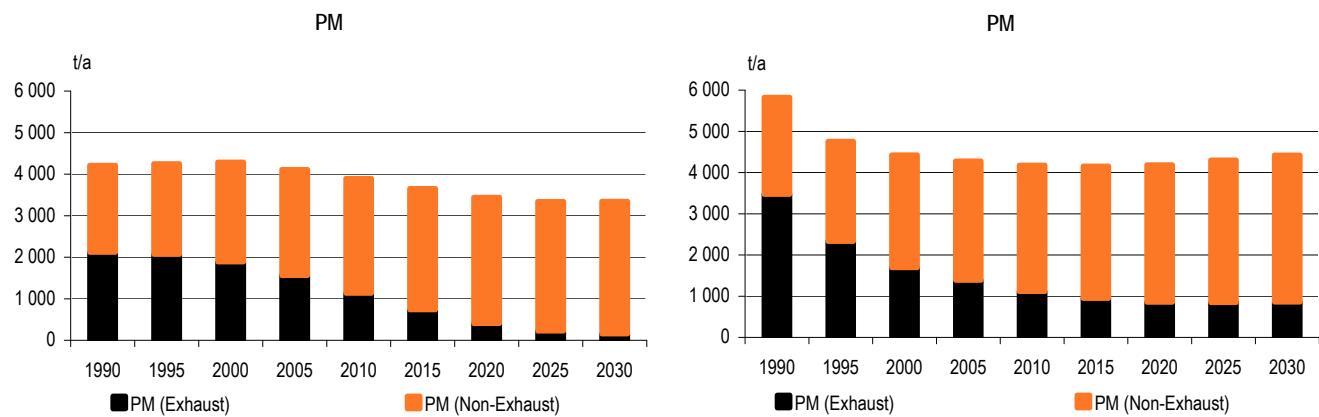

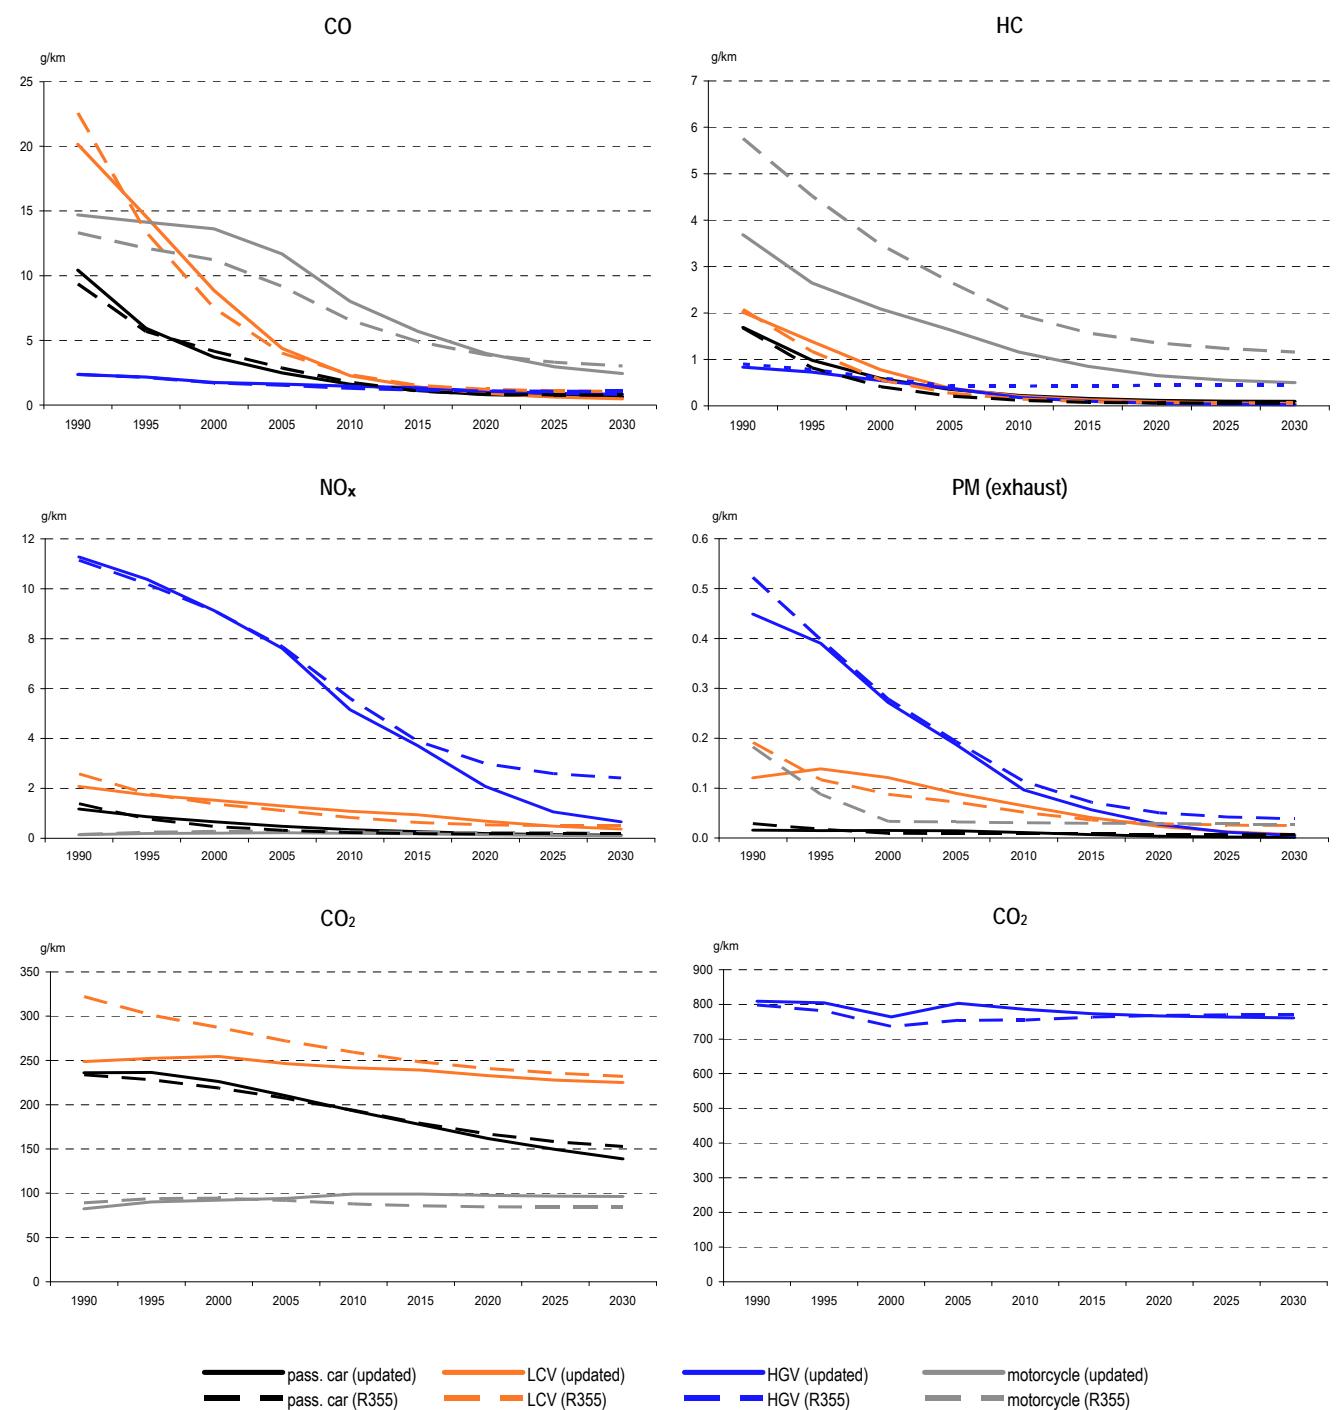

Fig. 13 > Comparison between updated emission trends and the figures in the previous report SAEFL 355

Fig. 14 > Comparison between updated PM emissions and figures in the previous report SAEFL 355*Trend as per Report 355.**Updated trend.*

4.2.2 Emission factors trend

The updated emission factors do not vary greatly from the earlier calculations (cf. Fig. 15). The most striking change concerns motorcycles, for which the level of HC emissions has been lowered. However, it is still well above that of all other vehicle categories. Another notable change concerns the sharp reduction of NO_x emission factors for heavy duty vehicles from 2014 onwards, which is attributable to the introduction of Euro-VI limit values.

With respect to CO₂ emission factors, the efficiency gain for passenger cars now also takes effect. For light commercial vehicles, the CO₂ emission factors for older models have been adjusted sharply downwards, and at the same time the reduction rates have also been reduced, so that the emission levels for future vehicles are similar to those indicated in Report 355. The fact that the CO₂ level increases slightly for motorcycles is primarily due to the shift in favour of heavier models.

Fig. 15 > Development of emission factors compared with the figures in the previous report SAEFL 355

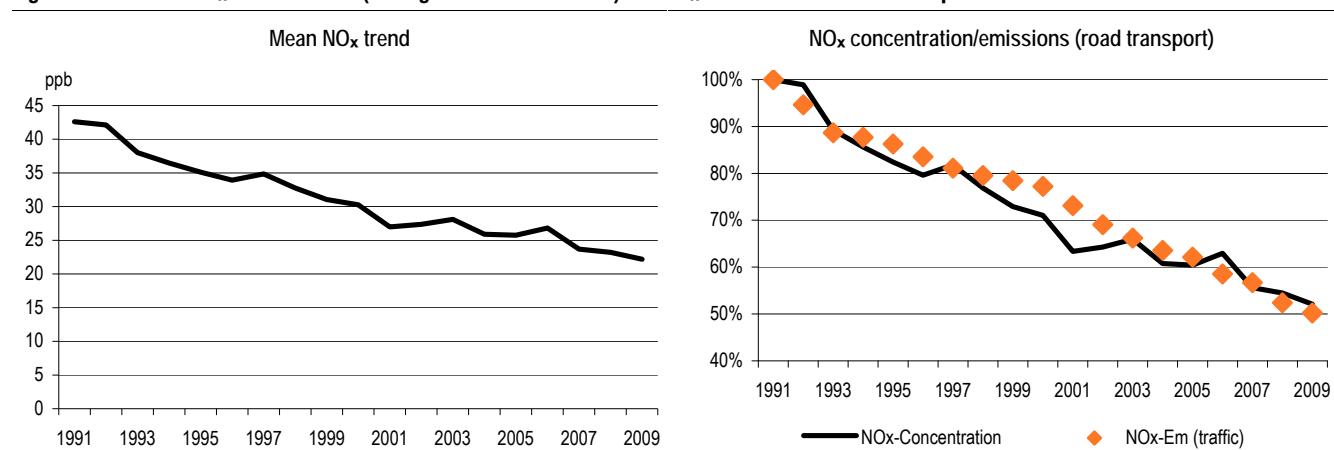

4.3

Comparison with air quality trends

Emission calculations have to be based on models that in their turn are based on measurements (namely of the emission behaviour of the vehicles in the laboratory), but also on other source data (e.g. traffic volumes) and a variety of additional assumptions of an empirical nature. The question nonetheless arises as to how reliable the results are. We can obtain an indicative validation by comparing the trends of emissions and air pollution levels over extensive time frames. Shorter periods cannot be used for such a comparison because weather conditions fluctuate considerably from year to year and thus have an influence on air pollution levels.

Fig. 16 shows the progress of air quality and overall emissions of nitrogen oxides (NO_x) from road transport in Switzerland since 1991 (the year in which the expanded air quality measurement network was put into operation). For the air pollution level, the figures represent the average for all stations on the National Air Pollution Monitoring Network (NABEL) except Jungfraujoch. 1991 has been designated as 100 percent. As we can see, the air pollution levels trend and the development of road transport emissions are very similar. (Road transport is the main source of NO_x emissions). In the period up to 2009, both air pollution levels and emissions fell by almost 50 percent in accordance with the model calculations.

Fig. 16 > Trend in NO_x concentration (average for NABEL stations) and NO_x emissions from road transport

> Annexes

A1 Emission limit values

The emission calculations presented in this report are based on measurements carried out on vehicles, and not on emission limit values. Although the measurements were carried out on chassis dynamometers, they were obtained on the basis of real-world driving patterns (and not type approval cycles).

However, emission limit values nonetheless provide an indicator of the trend. The tables below depict the development of the emission limit values for the various vehicle categories (based on FOEN 2008). For further details, please refer to the cited source.

Explanations regarding the definition of light duty vehicles

In accordance with FAV 1¹²:

Group I

- a) Vehicles for carrying passengers. Maximum no. of seats, 9 (including driver); maximum load, 760 kilograms

Classification of light duty vehicles in accordance with FAV 1 (prior to 1996)

¹² Article 1.3, Ordinance on Exhaust Emissions from Light duty Vehicles, dated 22 October 1986 (status, 4 August 1988)

- b) Vehicles for carrying goods, maximum load 760 kilograms
 c) Vehicles as per a) and b), for the transport of both passengers and goods

Group II

- a) Vehicles for passenger transport with a load of more than 760 kilograms, and those with more than 9 seats (including the driver)
 b) Vehicles for carrying goods, with a capacity of more than 760 kilograms
 c) Vehicles for carrying passengers, with a maximum of 9 seats (including driver) and a maximum load of 760 kilograms, clearly differentiable from vehicles in a) and b) above

In accordance with TAFV 1 (from Euro-2)¹³:

Classification of light duty vehicles in accordance with TAFV 1 (with effect from 1996)

Class M

Motor vehicles intended for passenger transport, with at least 4 wheels:

- > Class 1: vehicles with a maximum of 9 seats (including driver)
- > Class 2: vehicles with more than 9 seats (including driver) and with a certified maximum weight of 5 tonnes
- > Class 3: vehicles with more than 9 seats (including driver) and with a certified weight of more than 5 tonnes

Class N

Motor vehicles intended for goods transport, with at least 4 wheels:

- > Class 1: vehicles with a certified maximum weight of 3.5 tonnes
- > Class 2: vehicles with a certified weight of more than 3.5 tonnes, up to a maximum of 12 tonnes
- > Class 3: vehicles with a certified weight of more than 12 tonnes

Class O

Trailers (including semi-trailers and central axle trailers)

Class "M"

Vehicles for passenger transport, with a total weight of ≤ 2.5 tonnes and a maximum of ≤ 6 seats

Classification of light duty vehicles (classes M and N1) in accordance with Directives 1994/12/EC (Euro-1/2) and 1998/68/EC (Euro-3)

Class "N1"

Vehicles with a total weight > 2.5 tonnes or > 6 seats. These are sub-divided into 3 unladen weight categories (defined as vehicle + full tank + 75 kilograms for driver):

- > Euro-1/2: unladen weight N1-I < 1.250 kg, N1-II 1.250–1.700 kg, N1-III > 1.700 kg
- > Euro-3: unladen weight N1-I < 1.305 kg, N1-II 1.305–1.760 kg, N1-III > 1.760 kg

¹³ Ordinance on the technical requirements of transport duty vehicles and their trailers (TAFV), dated 19 June 1995 (status, 15 October 2002)

Definition of vehicle categories, see page 15

Tab. 10 > Vehicle stock and start procedures

Trend in passenger car, light duty vehicle and motorcycle fleets, and estimated start procedures for each category (required for estimating cold-start excess). The number of stop procedures is required for calculating evaporation emissions after the engine has been turned off. These are equated with the number of start procedures.
The fleet data for heavy duty vehicles (trucks and semi-trailers), coaches and buses are not required for emission calculations, but form the basis for processing traffic quantity data.

Year	Fleets (in thousands)						Starts per vehicle and day			Million starts p.a.		
	Passenger cars	Light commercial vehicles	Heavy goods vehicles	Coaches	Buses	Motorcycles	Passenger cars	Light commercial vehicles	Motorcycles	Passenger cars	Light commercial vehicles	Motorcycles

A5-2

Emissions by emission type

Tab. 15 > Emissions in tonnes per annum – differentiated by emission type

This differentiation is only relevant for passenger cars, light commercial vehicles and motorcycles, since the other vehicle categories only produce hot emissions.

Emission	Year	Emission type	PC	LCV	MC

A6-6

HC emission factors by emission type and emission concept

Tab. 24 > HC emission factors by emission type and emission concept in grams per kilometre ("warm" and "running losses") or grams per start (additional cold start emissions) or grams per stop (hot/warm soak) or grams per vehicle and day (diurnal)

> Abbreviations, figures and tables

Abbreviations

2S

2-stroke engine

3-way-cat

Regulated catalytic converter

4S

4-stroke Otto engine

A/C

Air Conditioning

8

European Automobile Manufacturers Association

AGV

Ordinance on exhaust emissions

ARE

Federal Office for Spatial Development

ARTEMIS

Assessment and reliability of transport emission models and inventory systems (EU project within the scope of Framework Programme 5)

AT

articulated truck

auto-schweiz

Association of Swiss Automobile Importers

CH₄

Methane

CNG

Compressed natural gas

CO

Carbon monoxide

CO₂

Carbon dioxide

COPERT

Computer Programme to calculate Emissions from Road Transport

CO₂ (rep.)

Reported carbon dioxide (fossil caused CO₂ emission without consideration of admixtures of bio fuels)

COST

European Co-operation in the field of Scientific and Technical Research

COST 346

COST action: "Emissions and fuel consumption of heavy duty vehicles"

D

Diesel

D-A-CH

Co-operation between Germany, Austria and Switzerland on the preparation of emission fundamentals (Handbook of Emission Factors in Road Transport)

DETEC

Federal Department of the Environment, Transport, Energy and Communications

ECE

United Nations Economic Commission for Europe (UNECE)

EF/EFA

Emission factor

EFKO

Swiss Federal Vehicle Inspection Office

EGR

Exhaust Gas Recirculation

EMPA

Swiss Federal Materials Testing and Research Laboratories, Dübendorf

EPEFE

European Program on Emissions, Fuels and Engine Technologies

ESC

European stationary Cycle

ETC

European Transient Cycle

Euro-1, 2, 3, 4, 5, 6

European exhaust regulations for light duty vehicles

Euro I, II, III, IV, V, VI

European exhaust regulations for heavy duty vehicles

FAV 1, 2, 3	NEDC
Federal ordinances on exhaust emissions (up to 1996)	New European Driving Cycle
1 = Light duty vehicles,	NO₂
2 = Heavy duty vehicles,	Nitrogen dioxide
3 = Motorcycles	
FAV 4	NH₃
Ordinance on Motorcycle Exhaust Emissions	Ammoniac
FC	NIR
Fuel consumption	Non-ionising radiation
FOEN	NMHC
Swiss Federal Office for the Environment	Non-methane hydrocarbons
FSO	NO_x
Federal Statistical Office	Nitrogen oxides
HBEFA	P
Handbook of Emission Factors for Road Transport	Petrol
HC	Pb
Hydrocarbons	Lead
HDV	PC
Heavy duty vehicle (> 3.5 t total weight; = general term for heavy goods vehicles and buses)	Passenger car
HGV	PF
heavy goods vehicles (rigid trucks, trucks with trailers and articulated trucks)	Particle filter
HVF	PHEM
Swiss performance-related heavy vehicle fee	Passenger car and heavy duty vehicle emissions model (developed by Technical University Graz)
LCV	PM
Light commercial vehicle (< 3.5 t), incl. small buses, utility vehicles, caravans, etc.	Particulate matter
LMC	PM exhaust
Light motorcycle (< 50 cc)	Particles in exhaust
MC	PM non-exhaust
Motorcycle	Particles resulting from abrasion and resuspension
MOFIS	PN
Motor Vehicle Information System of the Swiss vehicle inspection office	Particle number
NABEL	RL
National Air Pollution Monitoring Network	Running losses (evaporation losses during travel)
N₂O	RT
Nitrous oxide (laughing gas)	Rigid truck

¹⁴ TAFV 1: Ordinance of 19 June 1995 on the Technical Requirements for Transport Vehicles and their Trailers (SR 741.412). This Ordinance integrates the following standards into Swiss legislation:
 – «Euro-2» for light motor vehicles (Directive 70/220/EEC, version 94/12/EC and/or 96/69/EC) and «Euro-II» for heavy motor vehicles (Directive 88/77/EEC, version 91/542/EC);
 – «Euro-3» and «Euro-4» (Directive 98/69/EC for light motor vehicles) and «Euro-III/IV/V» (Directive 1999/96/EC for heavy motor vehicles).
 TAFV 3: Ordinance on the technical requirements of motorcycles, light, small and three-wheeled motor vehicles, dated 2 September 1998 (SR 741.414); «Euro-1» (in accordance with Directive 97/24/EC, and «Euro-2» and «Euro-3» (in accordance with Directive 2002/51/EC) have been integrated into this ordinance.
